‘To be or not to be’:
*Education for Clinical Practice in Risk Assessment of suicide behavior*

Proposer and Chair: Amresh Shrivastava

Amresh Shrivastava

Megan Johnston

Charles Nelson

1. Assistant Professor, Department of Psychiatry, University of Western Ontario, London, ON, Canada
3. Adjunct Clinical professor, Department of Psychology, University of Western Ontario, London, ON, Canada
2. University of Toronto

Regional Mental Health Care. St.Thomas, ON, Canada
Q1. SCOPE & LIMITATIONS OF CONTEMPORARY RISK-ASSESSMENT PRACTICES.

Q2. MAXIMIZING THE OUTCOME OF RISK — ASSESSMENT PRACTICES IN CLINICAL PSYCHIATRY.

Program Objectives:

- To review significance of suicide and risk assessments in clinical practice
- To review challenges of managing suicide behavior in clinical practice
- To understand concept of risk
- New risk assessment scale
Agenda

• Introduction
• Sharing experiences
• Identifying gaps in risk assessment
• Video based exercise of assessment
• Analysis and discussion
• Presentation 1 for 20 mts
• Video based exercise
• Hands on experience with new scale
• Presentation 2 x 20 minuets
• Q & A
• Volunteer based assessment
• Application of concept of risk
• Discussion & take home message
• Feed back/evaluation
SIGNIFICANCE OF SUICIDE AND RISK ASSESSMENTS IN CLINICAL PRACTICE
Suicide is a global public health problem, affecting more than a million people every year.
Suicide in Canada

High risk groups: Need for new strategies for prevention

General Rick Hillier Chief of the Canadian National Defence staff.
Canada’s Silent Tragedy

Rate has tripled in 40 years
Male : female = 3:1

Source: Suicide in Canada (1994), Mental Health Division, Health Services Directorate, Health Canada.
Suicide in Canada
High risk groups: Need for new strategies for prevention
54% between 30 to 50 years; & 25% between 55 to 90 years

Medical know-how raises doctors' suicide rate
Physicians' access to drugs, stigma of mental illness contribute to problem

Source: Statistics Canada
There is evidence of limitations in assessment of suicide for patients coming to services.
Treatment of mental disorder in universally advocated for prevention of suicide as up to 90% suicides arise from mental illnesses. It is therefore important that patients who seek services are well looked after.
Background

- WHO estimated that 10.4% of the population seriously considers suicide at some point in their life time while approximately 4.2% actually attempt suicide.

- In Canada, specifically, the suicide rate is between 8 and 10 per 100,000, which has been constantly rising. In the past 40 years the Canadian suicide rate has tripled.

- WHO stated reduction in the suicide rate is attainable if appropriate treatment is provided.

Facts.. About Suicide

• Suicide happens in people who have not contacted the services ever

• .... happens amongst people who established contact .. ..suicide victims do contact health services some weeks, months or even years before their suicide

• Recognition of risk as clinical pathological parameter

• Majority of malpractice litigation are arising from incident of suicide.

• Suicide risk assessment is a key competency required by all mental health professionals.

Prevention needs to target:
1. General Population
2. Health care system

Suicide

Within the Health & Social care system

Outside Health System
1 in 6 completed suicides are patients in psychotherapy,
50% of completed suicides have had previous experience in psychotherapy
1 of every 2 psychiatrists will lose a patient to suicide across (mean) 19.3 years practice
30% psychiatric residents across 4 years’ residency
1 of every 4 psychologists will lose a patient to suicide across (mean) 18.5 years practice
17% of psychology interns across 5.2 by internship
What is the purpose of risk assessment?

- Establish clinical needs
- Prediction of an attempt
- Decide level and quality of care
- Management issues
- Policy matters
- Patient safety
- Standard of care
- Component of suicide prevention
**Outcomes in Risk Assessment**

Clinical outcomes in management of suicide behavior depends on:
1. quality of assessment
2. quality of intervention

<table>
<thead>
<tr>
<th>Risk assessment quality Possible scenario</th>
<th>Intervention &amp; monitoring</th>
<th>Outcome</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. High quality risk assessment</td>
<td>High quality management and monitoring</td>
<td>Still client attempts or commits</td>
</tr>
<tr>

<td>Resource constrains, inadequate management</td>
<td>Incident</td>
</tr>
<tr>
<td>3. Poor risk assessment</td>
<td>Intervention and monitoring was inadequate</td>
<td>Incident</td>
</tr>
</tbody>
</table>
High suicide in recently discharged patients

- The first week and the first day after discharge were particular high-risk periods.
- Risk factors:
  - a history of self-harm,
  - recent last contact with services and expressing clinical symptoms at last contact with staff.
- Suicide cases:
  - 1) were more likely to have initiated their own discharge and
  - 2) to have missed their last appointment with services.
- Less likely to die by suicide:
  - Patients who were detained for compulsory treatment at last admission, or
  - who were subject to enhanced levels of aftercare, were

2008

Died within one month
Died before FIRST F/U

N=238, death by suicide within 3 months of discharge
The immediate post-discharge period carries a high risk of suicide for psychiatric patients. Hong Kong

In-patients

• 13-year follow up period
• The suicide risk of in-patients is distinctly higher than in the general population.
• A better assessment of suicide risk before regular leave periods could lead to a decrease of suicides in in-patient settings,

Suicide in First episode

- 18-24 years. First Episode Psychosis
- Predictors of suicide attempt were:
  - previous attempt (odds ratio (OR)=45.54,
  - sexual abuse (OR=8.46,
  - comorbid polysubstance (OR=13.63)
  - greater insight (OR=0.17)
  - lower baseline Global Assessment of Functioning (OR=0.96)
  - lower Occupational and Functional Assessment score OR=0.98)
  - longer time in treatment (OR=1.05)

What do we teach psychiatric residents about suicide? A national survey of chief residents.

• (91%) national programs offered formal teaching on suicide care;
• Grand rounds (85%) and Case conferences (80%) - popular methods for teaching.
• Even the topics most commonly taught, such as
  – risk factors,
  – recognizing early warning signs, and
  – standards of clinical care,
were judged to warrant more attention by many residents.
• Commonly identified barriers to teaching included the lack of audio or video teaching materials and relevant texts.

Skills training for risk assessments needs to find a place in ER medicine

Service provisions for prevention are expensive: An Arbor study, N=100,000 VA patients

| Study assessed frequency of high-risk periods, levels of monitoring provided and estimated costs of providing monitoring (FDA recommendation) | Completed an average of 2.4 monitoring visits during the 12-week period after antidepressant 4.9 visits after psychiatric hospitalization. | Providing intensive monitoring would cost an - additional $408-$537 & - $313-$341 for each high-risk period respectively - During fiscal year 2004 $183-$270 million. |

Valenstein M et al, Service implications of providing intensive monitoring during high-risk periods for suicide among VA patients with depression. Psychiatr Serv. 2009 Apr;60(4):439-44
Most people use only clinical judgment. Clinical practices for better outcome in management of suicide behavior:

1. Identifying gaps
2. Improving intervention
3. Improving assessment
4. Education for risk assessment
Identifying the gaps

- Patient: compliance, availing the services
- Family: identification, compliance
- Family physician: assessments
- Community team: continuity, risk-management, intervention
- Service provider: treatment & monitoring

Partnerships in care
Limitations in Risk Assessment

• There are too many factors and too many variations on the subject.
• Research has highlighted that perhaps a new definition of suicide needs to be found.  
• Prediction of suicide behavior has been a core area of research in suicidology.
• Several psychological & biological Markers have been proposed.
• Neither are free from false positive and false negative results
• Conventional method has been a thorough clinical assessment which get enriched by aid of structured interviews.
• Scales are useful: either self-administered, clinician administered or computer-based

• Most clinicians combine clinical experience with evidence–based research.
• Substandard suicide risk assessment often relies on clinical experience alone.
• No single source or authority defines the standard of care in suicide risk assessment.  
• It is important that clinicians are able to engage such people and identify immediate risk factors and clinical treatment needs.  
• Development of an assessment instrument to measure the effectiveness of suicide risk assessment and training is therefore likely to assume importance.
• Training effects do modify quality of assessment. However such attempts have not been able to demonstrate an ideal form of assessment

CHALLENGES IN PRACTICE OF SUICIDIDOLOGY
PROBLEMS ARISING FROM INADEQUATE RISK ASSESSMENT

Patient: incident, loss, disability, repeat suicide, clinical consequences

Organization: loss of reputation, malpractice litigations, lower standard of care

Physician: clinical frustration, litigation, administrative problems

Legal
Clinical
Coping with challenges of legality in suicidology

• Courts have tended to review 3 criteria in determining malpractice negligence in cases of suicide:
  – failure to determine the imminence of the suicidal behavior
  – if high risk suicide factors were identified and appropriate steps taken
  – thoroughness of the treatment plan and its implementation

Dignity and liberty---Liberty should not be compromised any more than is essential—even when suicide is a possibility.
Special populations

- Suicide is no longer limited to mental health settings
- Special high-risk populations are clearly becoming newer challenges in the task of suicide prevention. Some of the high-risk groups are: teen age, post-partum, old age, substance abuse, chronic medical illness, trauma & disaster, emotional & sexual abuse, mental disorders.

Risk assessment across treatment settings

- Rising incidence of suicide attempts have been observed in a wide variety of clinical & social settings e.g. schools, universities, prisons, correctional facilities & health services.
- To provide effective intervention & prevention, we require adequate tools and skills for assessment which can be effectively applied by a range of professionals.
- There is a serious lack of skilled professionals with adequate knowledge & expertise in most of the social & non-psychiatric settings.
Circumstances in which a suicide assessment may be indicated

• Emergency department or Crisis evaluation
• Intake evaluation
  – inpatient or
  – outpatient
• Before a change in observation status or treatment setting
  – (discontinuation of one-to-one observation)
• Abrupt change in clinical presentation
  – (either precipitous worsening
  – or sudden, dramatic improvement)

• Anticipation or experience of a significant interpersonal loss or psychosocial stressors
  – e.g. divorce,
  – finance, or
  – humiliation
• Onset of a physical illness
  – particularly life-threatening,
  – disfiguring or
  – associated with severe pain or loss
Step-by-Step Model for Assessing and Revising Suicide Policies, Procedures, and Practice

1) Know the relevant laws and ethics around suicide, confidentiality, informed consent, involuntary commitment.
2) Maintain a written policy and procedure statement on risk management with suicidal patients
3) Assure clinical competence
4) Assure adequate documentation of work with suicidal patients
5) Establish the relevant resources for clinical staff
   1) Clinical consultation
   2) Legal consultation
   3) Malpractice insurance coverage
   4) Develop relevant resource library
   5) Maintain list of outpatient, inpatient and emergency resources

Assessment Suicide

I. Assessment of patients with suicidal behavior
   A. Collection of vital information
      (Review & synthesis of Available Evidence)
      - Conduct a Thorough Psychiatric Evaluation
      - C. Specifically Inquire About Suicidal Thoughts, Plans, and Behaviors
      - D. Establish a Multiaxial Diagnosis
      - E. Estimate Suicide Risk
      - F. Additional Considerations When Evaluating Patients in Specific Treatment Settings
   B. I.Assessment

II. Psychiatric management
   A. Establish and Maintain a Therapeutic Alliance
   B. Attend to the Patient’s Safety
   C. Determine a Treatment Setting
   D. Develop a Plan of Treatment
   E. Coordinate Care and Collaborate With Other Clinicians
   F. Promote Adherence to the Treatment Plan
   G. Provide Education to the Patient and Family
   H. Reassess Safety and Suicide Risk
   I. Monitor Psychiatric Status and Response to Treatment
   J. Obtain Consultation, if Indicated

III. Specific Treatment modalities
   A. Somatic Therapies
   B. Psychotherapies

IV. Documentation and risk Management
   - APA Practice Guidelines: Assessment of patients with suicidal behaviors
II. Assessment of Patients With Suicidal Behaviors

A. Overview
B. Conduct a Thorough Psychiatric Evaluation
C. Specifically Inquire About Suicidal Thoughts, Plans, and Behaviors
D. Establish a Multiaxial Diagnosis
E. Estimate Suicide Risk
F. Additional Considerations When Evaluating Patients in Specific Treatment Settings
Il- assessment of patients with suicidal behavior

1. Identify specific psychiatric signs and symptoms

2. Assess past suicidal behavior, including intent of self-injurious acts

3. Review past treatment history and treatment relationships

4. Identify family history of suicide, mental illness, and dysfunction

5. Identify current psychosocial situation and nature of crisis

6. Appreciate psychological strengths and vulnerabilities of the individual patient

B- conduct a thorough psychiatric evaluation
Estimation of Suicide Risk

Suicide and suicidal behaviors cause severe
• personal,
• social, and
• economic consequences.

most individuals with suicidal thoughts or attempts will never die by suicide.

This rarity of suicide, even in groups known to be at higher risk than the general population, contributes to the impossibility of predicting suicide.

suicide and suicidal behaviors are statistically rare, even in populations at risk.
Suicide is a Low Base Rate Behavior

In the general U.S. population per year, (2).(3).
Estimation of Suicide Risk
the ‘factors are not the focus of treatment’

Non-modifiable
(Past history, family history, and demographic characteristics)
Financial difficulties or unemployment can also be difficult to modify, at least in the short term.
Risk factors are ‘additive’ & ‘synergetic’

While risk factors are typically additive (i.e., the patient's level of risk increases with the number of risk factors), they may also interact in a synergistic fashion.

• For example, the combined risk associated with comorbid depression and physical illness may be greater than the sum of the risk associated with each in isolation.
  • At the same time, certain risk factors, such as
    • a recent suicide attempt (especially one of high lethality),
      • access to a firearm,
      • presence of a suicide note,
    • should be considered serious in and of themselves, regardless of whether other risk factors are present.
Weighting of risk factors in suicide prediction
it is impossible to accurately predict suicide.

Statistical models may be valuable in the epidemiological and research arenas
Suggest clinically important risk factors that, if identified, are potentially amenable to treatment.
However, given the low base rates of suicide in the population, accurate prediction of suicide remains impossible,
Consequently, the psychiatric assessment, in combination with clinical judgment, is still the best tool for assessing suicide risk.
B. Psychiatric Assessment Techniques

- Tools Measure various aspects of suicidal thoughts and behaviors as well as symptoms associated with suicide.
- Reliable and have adequate concurrent validity
- Usefulness and generalizability in clinical practice are questionable.
  - tested in non-representative samples
  - have not been adequately tested in subpopulations
  - Not many have been tested in prospective studies, [have shown very low positive predictive validity and high rates of false positive]

- Scales are of value in learning to develop a thorough line of questioning about suicide
Rating scales for risk

- The Scale for Suicide Ideation
- The Suicide Behavior Questionnaire (SBQ)
- The Suicide Intent Scale
- Reasons for Living Inventory
- Risk-Rescue Rating,
- Suicide Assessment Scale,
- Thematic Apperception Test

- General Health Questionnaire
- Shneidman psychological pain assessment
- Beck Hopelessness Scale
- Hamilton Depression Rating Scale
- Beck Depression Inventory.
Rating scales

- Because of their
  - high rates of false positive and
  - false negative findings and
  - their low positive predictive values,
  - these rating scales cannot be recommended for use in clinical practice in estimating suicide risk.

A recent evaluation concluded:
“no single instrument was able to accurately predict suicide risk without a significant amount of error” (Bisconer & Gross, 2007).
An important part is developing assessment instruments which can successfully differentiate between individuals at serious risk and those who are not.

Ducher JL, Dalery J.  
[Correlations between Beck's suicidal ideation scale, suicidal risk assessment scale RSD and Hamilton's depression rating scale]  
Encephale. 2008 Apr;34(2):132
Comprehensive assessment of suicide

Level I:
1. Clinical data,
2. Patients account, Relatives/informant’s account,
3. Background details, 4. MSE,
5. Frequent review.

Level II:
Structured tools for Risk assessment

Level III:
Evidence based clinical decisions

Level IV:
Adequate documentation

Level V:
Qualitative communication
Comprehensive assessment of suicide

Level I:
1. Clinical data,
2. Patients account, Relatives/informant’s account,

Level II: Structured tools for Risk assessment

Level III: Evidence based clinical decisions

Level IV: Adequate documentation

Level V: Qualitative communication
REVIEW OF CONCEPT &
New Measurement Scale:
SIS-MAP
Construction of new scale

Development of an ‘assessment instrument’ contributes to measure the effectiveness of suicide risk assessment effect of training in skill building.

- We attempted a framework of concept based upon current evidence to construct an instrument to assess risk in order to address the issue of:
  - Current risk
  - Ability to predict suicidality
  - Guide patients disposition seen in crisis
  - Guide in planning and management of care
Quantifying Risk (cumulative)

- State
  - Relationship Crisis
- Cross-sectional
- Longitudinal
- Trait
- Recent Loss
- Attempted suicide
- Psychiatric Illness
- Childhood experience
- Family History
- Personality factors

Age 30
Cumulative
Age 5 years
A conceptual framework for suicide causation

- Biological
  - Genetic-familial
- Psychological, Developmental
- Social-Environmental
- Spiritual
- Pathological states: Mental, Physical, Substance abuse, morbidity AND
- Protective factors

References:

Conceptual framework

• Concept of risk has been questioned since long
• It appears that it is a continuously evolving process.
• Suicide is a multidimensional concomitant of psychiatric diagnoses; especially mood disorders, and is complex in both its causation and in the treatment of those at risk.
• Risk and protective factors tend to be fairly consistent worldwide, with some cultural variation.
• Even with standardized assessment and prediction scales (such as the Hamilton or Beck depression inventories), suicide prediction results in about 30% false positives.\(^\text{12}\)

• The present work conceptualizes understanding of risk in a new direction. An electronic search about risk factor elicited total 76 factors reported which were from biological, social, psychological, environmental, psychiatric, medical, cultural, spiritual and familial domains.

Risk is measured in relation to strength

Proposed concept

Vulnerability

Resilience

Risk factors

Protective factors
Stress-diathesis model forms the theoretical context of Risk-Vulnerability hypothesis.
Current concept of risk

Risk factors
- Poor coping, mental, physical illness, SUD

Protective factors
- Spirituality, belief, attitude
- Support system
- Personality development

Current stressors

Trait risk: fixed factors

State Risk: modulating factors

Current absolute risk
Components of RISK

- Presence of mental illness
- Adverse childhood experiences
- Genetics/familial
- Trait risk: determines lifetime risk
- Learned coping mechanism
- Recent life events, loss
- Lack of support system
- Current mental state
- State risk: determines current or situational response
- Personal belief
Development of scale

- consideration of the most prominent risk and resilience factors identified by 16 experts in the field
- Twenty one commonly mentioned indicators,
- incorporate most of known risk factor
- The SIS-MAP measures an individual's current level of risk in five different domains:

(Pope & Vasquez, 2007).
Disposition

Clinical disposition
- Follow up & specialized resources
- Crisis plan developed
- Client referred to outpatient services or crisis unit follow up
- Client referred to specialized addiction services
- Client referred to women’s shelter
- Client referred to safe beds

Resource utilization

Involuntary. MHA
- Hospitalized
- Referral to A.C.T or
- Community agencies CMHA
- Referral back to family physician

Voluntary
- Referral to A.C.T or
- Community agencies CMHA
- Referral back to family physician

- Demography
- Psychosocial Stressors
- Biological factors
- Family History
- Clinical ratings, observations
- Primary/recency factors

- Ideation
- Planning
- Assessment
The scale: SIS-MAP

Psychological Domain, continued

Have you attempted to kill yourself?  \(\text{If no, skip to question P...}\)
Did you want to die?
Were you certain that you wanted to die?
Did you want attention from someone?
At the time of your attempt, were you depressed?
At the time of your attempt, were you angry with yourself?
Do you want to attempt again?
Was the method damaging to your body?
Do you regret it?
Did you speak to someone before making the attempt?
Did you inform anyone afterwards?
Did you leave a suicide note?
Are you still stressed about it?
Are you feeling relieved?
Are you feeling safe in the hospital? (if applicable)
Do you feel safe in your house?
Do you feel guil or shame?
Was your attempt because of your mental illness?
Is it because of your social or psychological situation?
Who do you hold responsible for the attempt?
Do you still have suicidal ideas?
Do you want to seek help?
Do you think you can deal with it yourself?

Management of ideation:
M. How often do you get these thoughts?
How intense are these thoughts?
Can you cope with distressing thoughts of suicide?
Do you wish to be killed?
Do you wish to die?
Do you fear losing control and attempting suicide?
Are you uncertain about the nature of your suicidal thoughts?
Do you believe in communicating about your suicidal thoughts to others?
Do you believe in seeking help for suicidal thoughts?

Assessment of current state of suicidality (consider current thought processes under recent attempt)
A. Do you currently feel suicidal?
Do you feel hopeless?
Do you feel helpless?
Do you feel worthless?
Do you feel sad or depressed?
Do you feel any guilt?

1 Client should be instructed to answer these questions with reference to the most recent attempt
2 Unauthorized usage prohibited. Contact dr.amresh@gmail.com or charles.nelson@ljhc.london.on.ca for more information.

Methods

Peer review → Approval → Feasibility study

Education → Inter-rater reliability. → Training

Pilot field trial: Setting, Population → Outcome & Psychometric properties → Further trial across treatment settings
Psychometric Properties

• Inter-rater reliability

• The inter-rater reliability of the scale was assessed by videotaping a case vignette in which a therapist administers the structured interview to a mock client.

• Twenty clinicians were then familiarized with the SIS-MAP and were asked to score the mock client using this scale according to what they observed in the videotaped interview.

• The twenty clinicians included registered nurses, social workers, occupational therapists, and psychometrists.

• SIS-MAP has shown an inter-rater reliability between 0.71 and 0.81 (x=.76) N=20, p<.001.

• In the field trial it has demonstrated a specificity of 78.1%, sensitivity of 66.7% and validity of correctly classifying 74%. On comparison with other popular scales SIS-MAP comes out as parallel on all parameters.

SPS = Suicide Probability Scale (Cull & McGill, 1988); ASIQ = Adult Suicidal Ideation Questionnaire (Reynolds, 1991); BDI-II = Beck Depression Inventory II (Beck, Steer, & Brown, 1996)
Results:

Correlations among Variables and Admission Status

- Whether individuals were admitted or not was correlated with various outcome measures.

Analyses demonstrated that admission status was correlated with subtotals in the protective domain ($r = -0.333, p < 0.05$), suggesting that individuals with higher levels of resilience factors were less likely to be admitted, a key assumption of the SIS-MAP.

Additionally, the individual items of previous suicide attempts and the presence of psychosis were correlated with admission status ($r = 0.368, p < 0.05$, and $r = 0.321, p < 0.05$ respectively).
Classifying Individuals Using the SIS-MAP

The specificity of the scale (correctly identifying individuals who did not require admission) was 78.1%

while the sensitivity of the scale (correctly identifying individuals who required admission) was 66.7%.

The false positive rate was 33.3% while 21.9% of cases resulted in a false negative.
SIS-MAP

Clinical Cut-Offs for Level of Care Needed

Scores 13-23 = outpatient follow-up highly recommended

Scores 23-33 = consider psychosis, previous suicide attempts, and protective factors

Scores >33 = admit highly recommended
Future directions

We hope to generate a quotient ratio of risk and protective factor giving visual expression on graphic representation of absolute risk for easy applicability. The concept and data needs to be validated.
Strategies to improve quality of risk assessment: WHO Recommendations

1. Requires a public health approach.
2. The burden of suicide is so large that prevention could be considered the responsibility of an entire government, under the leadership of the health ministry.
3. Suicide-prevention programmes are needed and should consider specific interventions for different groups at risk.
4. Health-care professionals, especially in the emergency services, should be trained in the effective identification of suicide risk and proactive collaboration with mental health services.
5. Both health professionals and the general public should be educated about suicide as early as possible, with a focus on both risk and protective factors.
6. Policy-oriented research on and evaluation of suicide prevention programmes is needed.
7. The mass media should be involved in suicide prevention via training, and use of the WHO guidance on media treatment of suicide.
