Abstract  Road accident is a special case of trauma that constitutes a major cause of disability, untimely death and loss of loved ones as well as family bread winners. Therefore, predicting the likelihood of road accident on highways with particular emphasis on Lagos – Ibadan express road, Nigeria in order to prevent accident is very important. Various attempts had been made to identify the cause(s) of accidents on highways using different techniques and system and to reduce accident on the roads but the rate of accident keep on increasing. In this study, the various techniques used to analyse the causes of accidents along this route and the effects of accidents were examined. A technique of using data mining tool to predict the likely occurrence of accident on highways, the likely cause of the accident and accident prone locations was proposed using Lagos – Ibadan highway as a case study. WEKA software was used to analyse accident data gathered along this road. The results showed that causes of accidents, specific time/condition that could trigger accident and accident prone areas could be effectively identified.

Keywords  Data Mining, Decision Tree, Accident, WEKA, Data Modelling, Id3 Algorithm, Id3 Tree, Functional Tree Algorithm

1. Introduction

Road accident is a special case of trauma that constitutes a major cause of disability and untimely death. It has been estimated that over 300,000 persons die and 10 to 15 million persons are injured every year in road accidents throughout the world. Statistics have also shown that mortality in road accidents is very high among young adults that constitute the major part of the work force. In actual fact, accidents kill faster than AIDS and it gives no preparatory time to its victims. In order to combat this problem, various road safety strategies have been proposed and used. These methods mainly involve conscious planning, design and operations on roads. One important feature of this method is the identification and treatment of accident prone locations commonly called black spots; black spots are not the only cause of accidents on the highway. Also various organizations such as Police High Way Patrol, Vehicle Inspection Officer (VIO), Federal Road Safety Commission (FRSC) among others are charged with the responsibility of maintaining safety thereby reducing road accidents. However, lack of good forecasting techniques has been a major hindrance to these organizations in achieving their objectives.

It is against this background that Decision Tree is being proposed to model data from road accident database to determine causes of accidents and accident prone locations using historical data collected from Ibadan-Lagos express road as reference point.

2. Objective

The primary objective of this research is to use data mining technique; decision tree to predict causes of accident and accident prone locations on highways using data collected on Lagos – Ibadan express way.

3. Methods

3.1. Data Mining

Data Mining is an interactive process of discovering valid and novel, useful and understandable patterns or models in large database (Han, Mannila and Smyth, 2001). Data Mining, according to Han, Mannila and Smyth (2001) is a process that uses a variety of data analysis tools to discover patterns and relationships in data that may be used to make a valid prediction. Data mining uses advances in the field of Artificial Intelligence (AI) and Statistical techniques. Therefore, decision tree is being used in this research.

3.2. Decision Trees
Decision Trees have emerged as a powerful technique for modelling general input/output relationships. They are tree-shaped structures that represent a series of roles that lead to sets of decisions. They generate rules for the classification of a dataset and a logical model represented as a binary (two-way split) tree that shows how the value of a target variable can be predicted by using the values of a set predictor variables. Decision trees, which are considered in a regression analysis problem, are called regression trees. Thus, the decision tree represents a logic model of regularities of the researched phenomenon.

3.3. Accidents along Lagos - Ibadan Express Way

Lagos to Ibadan Express road is one of the busiest roads in Africa. This is because Lagos was the capital of Nigeria until the seat of government moved to the Federal Capital Territory Abuja and also the headquarters of many national institutions while Ibadan is said to be the largest city in black Africa. The traffic along this route is very heavy because it is a gateway linkage of the heavy traffic going from the Northern, Eastern and Majority of Western states. The traffic along this route is very heavy because it is a gateway linkage of the heavy traffic going from the Northern, Eastern and Majority of Western states. Fig 3.1 shows the frequency of accidents between the distances of 1 and 40km from Ibadan to Lagos between January 2002 and December 2003. The statistics shows that having a means of predicting likely location of accident base on some input values is essential to advice on dangerous locations.

Figure 3.1. Graph of Frequency of Accidents against Month

Several works have been carried out by different researchers both on road accident analysis and forecasting, using Decision Tree and Artificial Neural Networks. Martin, Grandal and Pilkey (2000), analysed the relationship between road infrastructure and safety by using a cross-sectional time-series data base collected for all 50 U.S. states over 14 years. The result suggested that as highway facilities are upgraded, there are reduced fatalities. Gelfand (1991) studied the effect of new pavement on traffic safety in Sweden. The result of his study shows that Traffic accidents increased by 12% after one year of resurfacing on all types of roads. Akomolafe (2004) employed Artificial Neural Network using multilayer perceptron to predict likelihood of accident happening at particular location between the first 40 kilometers along Lagos-Ibadan Express road and discovered that location 2 recorded the highest number of road accident occurrence and that, tyre burst was the major cause of accident along the route. Ossenbruggen (2005) used a logistic regression model to identify statistically significant factors that predict the probabilities of crashes and injury crashes aiming at using these models to perform a risk assessment of a given region. Their study illustrated that village sites are less hazardous than residential and shopping sites. Abdalla et al (1987) studied the relationship between casualty frequencies and the distance of the accidents from the zones of residence. As might have been anticipated, the casualty frequencies were higher nearer to the zones of residence, possibly due to higher exposure. Akomolafe et al (2009) used geo spatial technology to identify various positions along major roads in Nigeria. The study revealed that the casualty rates amongst residents from areas classified as relatively deprived were significantly higher than those from relatively affluent areas.

3.4. Process of Data Mining

The process of data mining consists of three steps which are:

3.4.1. Data Preparation

This includes; Data collection, Data cleaning and Data transformation.

3.4.2. Data Modeling

This research considers the data of accident record between the first 40km from Ibadan to Lagos. The data were organized into a relational database.

The unknown causes in Table 3.2 may include other factors such as Law enforcement agent problems, attitude of
other road users, inadequate traffic road signs, traffic congestion and general vehicle conditions.

The sample data used covered the period of 24 Months, that is, January 2002 to December 2003 as indicated in Fig. 3.1.

The output variable is the location and the locations can be divided into three distinct regions tagged regions A, B and C, meaning we have three outputs. Where

First location 1 – 10km is Region A or location 1, Above10km – 20km is region B or Location 2 and above 20km is region C or Location 3.

The data sample used covered a period of twenty four Months starting from January 2002 to December 2003. The data were collected by Akomolafe (2004) and this is presented in Table.3.3.

### 3.4.3. Deployment

In this stage, new sets are applied to the model selected in the previous stage to generate predictions or estimates of the expected outcome.

Using Data Mining Technique to Predict Cause of Accident and Accident Prone Locations on Highways
4. Results

4.1. Analysis

The major step required to obtain result of the research was carried out by analysing the data using WEKA. WEKA is a collection of machine learning algorithms and data processing tools. It contains various tools for data pre-processing, classification, regression, clustering, association rules and visualization. There are many learning algorithms implemented in WEKA including Bayesian classifier, Trees, Rules, Functions, Lazy classifiers and miscellaneous classifiers. The algorithms can be applied directly to a data set. WEKA is also data mining software developed in JAVA it has a GUI chooser from which any one of the four major WEKA applications can be selected. For the purpose of this study, the Explorer application was used.

The Explorer window of WEKA has six tabs. The first tab is pre-process that enables the formatted data to be loaded into WEKA environment. Once the data has been loaded, the preprocess panel shows a variety of information as shown in figure 4.3 below.

![WEKA GUI Chooser](image1)

**Figure 4.1.** WEKA GUI chooser

![WEKA Explorer](image2)

**Figure 4.2.** WEKA Explorer
4.1. Weka Classifiers

There are several classifiers available in WEKA but Function Tree and Id3 were used in this study in case of Decision Tree. Prism Rule based learner was generated using WEKA. Attribute importance analysis was carried out to rank the attribute by significance using information gain. Finally, correlation based feature subset selection (cfs) and consistency subset selection (COE) filter algorithm were used to rank and select the attribute that are most useful. The F-measure and the AUC which are well known measures of probability tree learning was used as evaluation metrics for model generated by WEKA classifiers.

Several numbers of setups of decision tree algorithms have been experimented and the best result obtained is reported as the data set. Each class was trained with entropy of fit measure, the prior class probabilities parameter was set to equal, the stopping option for pruning was misclassification error, the minimum n per node was set to 5, the fraction of objects was 0.05, the maximum number of nodes was 100, surrogates was 5, 10 fold cross-validation was used, and generated comprehensive results.

The best decision tree result was obtained with Id3 with 115 correctly classified instances and 33 incorrectly classified instances which represents 77.70% and 22.29% respectively.

Mean absolute error was 0.1835 and Root mean squared error was 0.3029.

The tree and rules generated with Id3 algorithm are given thus:

4.2. Id3 Tree

5. Discussion

There are 50 rules generated from this tree. Rule 1-18 indicate the occurrence of accident in Location 3 and rule 19-50 also shows the occurrence of accident in location 2. This indicates that, location 2 has the highest number of road accident occurrence with Heavy-vehicle in the afternoon and during the dry season.

Rule 41 is the best one that can be used for prediction. The rule says that, Tyre burst is the cause of road accident with heavy vehicle within location 2 in the daytime and during the dry season.

6. Conclusions

Using WEKA software to analyze accident data collected on Lagos-Ibadan road, it was found that decision tree can accurately predict the cause(s) of accident and accident prone locations along the road and other roads if relevant data are gathered and analyzed as in this case.

In Decision Tree Performance analysis, the, dataset were experimented with two algorithms; Id3 and FT (function tree) For Id3 algorithm, there were 115 correctly classified instances and 33 incorrectly classified instances which represent 77.70% and 22.29% respectively. Mean absolute error was 0.1835 and Root mean squared error was 0.3029.

Also for functional tree algorithm (FT), total number of tree size was 5 with 105 correctly classified instances representing 70.27% and 44 incorrectly classified instances representing 29.73%.

From the detailed accuracy by class and confusion matrix, Id3 attained accuracy rate of 0.777 and FT attained accuracy rate of 0.703.
