Heteroclinic Solutions to an Asymptotically Autonomous Second Order Equation,
HETEROClinIC SOLUTIONS TO AN ASYMPTOTICALLY AUTONOMOUS SECOND ORDER EQUATION

GREGORY S. SPRADLIN

Abstract. A differential equation of the form \( \ddot{x}(t) = a(t)V'(x(t)) \) is studied, where \( V \) is a double-well potential with minima at \( x = \pm 1 \) and \( a(t) \to l > 0 \) as \( |t| \to \infty \). It is proven that under certain additional assumptions on \( a \), there exists a heteroclinic solution \( x \) to the differential equation with \( x(t) \to -1 \) as \( t \to -\infty \) and \( x(t) \to 1 \) as \( t \to \infty \). The assumptions allow \( l - a(t) \) to change sign for arbitrarily large values of \( |t| \), and do not restrict the decay rate of \( |l - a(t)| \) as \( |t| \to \infty \).

1. Introduction

Consider the autonomous second-order differential equation

\[
\ddot{x}(t) = lV'(x(t)),
\]

\[
x(t) \to -1 \text{ as } t \to -\infty, x(t) \to 1 \text{ as } t \to \infty.
\]

where \( l > 0, V \in C^2(\mathbb{R}, [0, \infty)), V(-1) = V(1) = 0, \) and \( V > 0 \) on \((-1, 1)\). The presence of \( l \) seems superfluous at this point; however, we will use it later. It is easy to show that (1.1)-(1.2) has a solution: multiply both sides of (1.1) by \( \dot{x}(t) \) and integrate, and conclude that \( \frac{1}{2} \dot{x}(t)^2 - lV(x(t)) \) is constant. Assuming that \( V(x) \leq c(1 \pm x)^2 \) for some \( c > 0 \) in a neighborhood of \(-1 \) and \( 1 \) respectively, then setting the constant equal to zero, we find that (1.1)-(1.2) has a solution, which solves the first-order equation \( \dot{x}(t) = \sqrt{2lV(x(t))} \). That solution is unique if we impose the condition \( x(0) = 0 \). From now on, we will refer to the unique solution of (1.1)-(1.2) with \( x(0) = 0 \) as \( \omega \).

\( \omega \) can also be characterized as the unique (modulo translation) minimizer of the functional

\[
F_l(u) = \int_{-\infty}^{\infty} \frac{1}{2} \dot{u}(t)^2 - lV(u(t)) \ dt \quad (1.3)
\]

over the affine space

\[
W = \{ u \in W^{1,2}_{loc}(\mathbb{R}) \mid u + 1 \in W^{1,2}((-\infty, 0]), \ u - 1 \in W^{1,2}([0, \infty)) \}.
\]

(1.4)

An interesting problem is to replace \( l \) by a nonconstant, positive coefficient function \( a(t) \) and find conditions on \( a \) under which

\[
\ddot{x}(t) = a(t)V'(x(t))
\]

(1.5)

2000 Mathematics Subject Classification. 34B40, 34C37.

Key words and phrases. heteroclinic, non-autonomous equation, bounded solution, variational methods.
with (1.2) has solutions. We must assume something: note that if \( a \) is continuous and increasing, then if \( x \) solves (1.1)-(1.2), then
\[
\frac{d}{dt} \left( \frac{1}{2} \dot{x}(t)^2 - a(t)V(x(t)) \right) = \ddot{x}(t)x(t) - a(t)V'(x(t))\dot{x}(t) - \dot{a}(t)V(x(t)) = -\dot{a}(t)V(x(t)) < 0.
\]

This is impossible.

There are many results concerning equations like (1.5) in which the analogue of \( a(t) \) is periodic, and homoclinic, heteroclinic, and multitransition solutions of the equations are found. See [6], [10]. There seems to be fewer results for the case

\[
(A_1) \ a(t) \to l > 0 \text{ as } |t| \to \infty
\]

In [2] (Chapter 2, Thm. 2.2) a solution is found for when \( 0 < a(t) \leq l \) for all \( t \in \mathbb{R} \). In [5] (Section 5, Example 1) a solution is found when the coefficient \( a(t) \) is definitively increasing with respect to \( |t| \). In [8], a solution is found in the case \( l \leq a(t) \leq L \) and \( L \) is suitably bounded from above. This result is a specific case of the result proven in this paper and is described more precisely later. In [9], a solution is found when \( a(t) \) is increasing on \([t_0, \infty)\) and decreasing on \((-\infty, t_0]\) for some \( t_0 > 0 \) and \( l - a(t) \) decays to zero slowly enough as \( |t| \to \infty \). In this paper, we find conditions on \( a \) which allow \( l - a(t) \) to change sign for arbitrarily large \( |t| \) and do not require any assumptions on the monotonicity of \( a \) or the decay rate of \( l - a(t) \) as \( |t| \to \infty \). In more related work, in [7] heteroclinic orbits to a nonautonomous differential equation are found that connect stationary points of different energy levels. In [4], heteroclinic solutions connecting nonconsecutive equilibria of a triple-well potential are found for a fourth-degree ordinary differential equation.

Let \( V \) satisfy

\[
(V_1) \ V \in C^2(\mathbb{R}, \mathbb{R})
\]

\[
(V_2) \ V(x) \geq 0 \text{ for all } x \in \mathbb{R}
\]

\[
(V_3) \ V(-1) = V(1) = 0
\]

\[
(V_4) \ V > 0 \text{ on } (-1, 1)
\]

\[
(V_5) \ V''(-1) > 0, \ V''(1) > 0
\]

Let
\[
\xi_- = \min \{ x \mid x > -1, V'(x) = 0 \},
\]
\[
\xi_+ = \max \{ x \mid x < 1, V'(x) = 0 \}.
\]

\( \xi_- \) and \( \xi_+ \) are well-defined by \((V_3)-(V_5)\). Define
\[
\nu = \min \left( \int_{-1}^{\xi_-} \sqrt{V(x)} \, dx, \int_{\xi_+}^{1} \sqrt{V(x)} \, dx \right) > 0.
\]

Let \( a : \mathbb{R} \to \mathbb{R} \) be a measurable function satisfying \((A_1)\) and
\[
(A_2) \ 0 < l \leq a(t) \leq L \equiv l + 4\nu \sqrt{l} / \int_{-1}^{1} \sqrt{V(x)} \, dx \text{ for all } t \in \mathbb{R}
\]

We will prove the following:
**Theorem 1.1.** Let $V$ and $a$ satisfy $(V_1)$–$(V_3)$ and $(A_1)$–$(A_2)$. Then (1.5), (1.2) has a solution taking values in $(-1, 1)$.

Note: if $V$ is even and $V > 0$ on $(-1, 0)$, then $L = l + 2\sqrt{l}$ in $(A_2)$. If $l = l$, we obtain the result of [8]. Due to a dearth of counterexamples, it is not known whether the upper bound on $a$ in $(A_2)$ is really necessary.

This paper is organized as follows: Section 2 lays out the variational methods used in the proof and an outline of the proof. Section 3 contains the proofs of some subordinate propositions and lemmas, with the most involved proposition concerning the convergence of Palais-Smale sequences of the functional associated with (1.5). Section 4 wraps up the proof of Theorem 1.1.

2. Variational Method and Outline of Proof

Define the functional $F : W^{1, 2}_{loc}(\mathbb{R}) \to [0, \infty]$ by

$$F(x) = \int_{-\infty}^{\infty} \frac{1}{2} \dot{x}(t)^2 + a(t)V(x(t)) \, dt.$$  \hfill (2.1)

By $(V_1)$–$(V_3)$, $F(x) < \infty$ for all $x \in W$. $F : W \to \mathbb{R}^+$ is Fréchet differentiable with

$$F'(x)u = \int_{-\infty}^{\infty} \dot{x}(t) \dot{u}(t) + V'(x(t))u(t) \, dt$$  \hfill (2.2)

for all $x \in W$, $u \in W^{1, 2}(\mathbb{R})$. Critical points of $F : W \to \mathbb{R}^+$ are solutions of (1.5), (1.2). We will show via a minimax argument that $F$ has at least one critical point.

Define

$$\mathcal{B} = F_1(\omega) > 0,$$  \hfill (2.3)

where $F_1$ is as in (1.3). A Palais-Smale sequence for $F$ is a sequence $(x_n) \subset W$ with $F(x_n)$ convergent and $\|F'(x_n)\| \to 0$ as $n \to \infty$, where $\|F'(x)\|$ is defined by the operator norm

$$\|F'(x)\| = \sup \{F'(x)u \mid u \in W^{1, 2}(\mathbb{R}), \|u\|_{W^{1, 2}(\mathbb{R})} = 1\}.$$  \hfill (2.4)

We will use the usual norm on $W^{1, 2}(\mathbb{R})$,

$$\|u\|_{W^{1, 2}(\mathbb{R})} = \left( \int_{-\infty}^{\infty} \dot{u}(t)^2 + u(t)^2 \, dt \right)^{1/2}.$$  \hfill (2.5)

The $W^{1, 2}(\mathbb{R})$-norm will be denoted simply by $\| \|$ from now on.

We will prove the following proposition:

**Proposition 2.1.** Let $(x_n) \subset W$ with $F'(x_n) \to 0$ and

$$F(x_n) \to b \in [0, \mathcal{B}] \cup (\mathcal{B}, \mathcal{B} + 2\sqrt{2}].$$  \hfill (2.6)

Then, there exists $\bar{x} \in W$ solving (1.5), (1.2) and a subsequence of $(x_n)$ (also called $(x_n)$) with $\|x_n - \bar{x}\| \to 0$ as $n \to \infty$.

It is interesting that the conclusion of Proposition 2.1 fails precisely when $b = \mathcal{B}$. To verify this, define the translation operator $\tau$ by $\tau_u(t) = u(t - a)$ for any $u : \mathbb{R} \to \mathbb{R}$ and $a, t \in \mathbb{R}$. Then the Palais-Smale sequence $(x_n) = (\tau_n \omega)$ satisfies $F(x_n) \to \mathcal{B}$ and $F'(x_n) \to 0$ as $n \to \infty$, but $x_n \to -1$ pointwise.

We use a minimax argument similar to that in [8]. Define

$$\Gamma = \{ \gamma \in C(\mathbb{R}, W) \mid \|\tau \omega - \gamma(t)\| \to 0 \text{ as } |t| \to \infty \}$$  \hfill (2.7)
and
\[ c = \inf_{\gamma \in \Gamma} \sup_{t \in \mathbb{R}} F(\gamma(t)). \] (2.8)
Clearly \( c \geq B \). We will show in Section 4 that \( c < B + 2\nu \sqrt{2} \). There are two cases to consider: \( c = B \) and \( c > B \). If \( c > B \), then a standard deformation argument shows that there exists a Palais-Smale sequence \((x_n)\) with \( F(x_n) \to c \) and \( F'(x_n) \to 0 \) as \( n \to \infty \). Applying Proposition 2.1, there exists a solution \( \hat{x} \) of (1.5), (1.2) and a subsequence of \((x_n)\) (also denoted \((x_n)\)) with \( \|x_n - \hat{x}\| \to 0 \) as \( n \to \infty \). If \( c = B \), then for every \( n \in \mathbb{N} \), there exists \( \gamma_n \in \Gamma \) with \( \sup_{t \in \mathbb{R}} F(\gamma_n(t)) < B + 1/n \). Choose \( t_n \in \mathbb{R} \) with \( \gamma_n(t_n)(0) = 0 \) and let \( x_n = \gamma_n(t_n) \). Since \( (F(x_n)) \) is bounded, we will show there exists a subsequence (also called \((x_n)\)) and \( x \in W^{1,2}_0(\mathbb{R}) \) such that \((x_n)\) converges to \( x \) locally uniformly and weakly in \( W^{1,2}([\tau, T]) \) for all \( T > 0 \). We will show in Section 4 that in fact \( x \in W^{1,2}([\tau, T]) \) and \( F(x) = B \). If \( x \) is a critical point of \( F \), then Theorem 1.1 is proven. Otherwise, let \( W(y) \) denote the gradient of \( F \) at \( y \) for all \( y \in W \); that is, for all \( y \in W \) and \( \varphi \in W^{1,2}(\mathbb{R}) \),
\[ (W(y), \varphi)_{W^{1,2}(\mathbb{R})} = F'(y)\varphi, \] (2.9)
where \((, )\) is the standard inner product on \( W^{1,2}(\mathbb{R}) \),
\[ (f, g)_{W^{1,2}(\mathbb{R})} = \int_{-\infty}^{\infty} f(t)\dot{g}(t) + f'(t)g(t) \, dt. \] (2.10)
Let \( \eta \) denote the solution of the gradient vector flow induced by the initial value problem:
\[ \frac{d}{ds} \eta(s, u) = -W(\eta(s, u)); \quad \eta(0, u) = u. \] (2.11)
We will show in Section 4 that \( \eta \) is well-defined on \([0, \infty) \times W\).

Recall that we have \( x \in W \) with \( F(x) \leq B \) and \( F'(x) \neq 0 \). Since \( F \) is nonnegative, there exists a sequence \((s_n) \subset \mathbb{R}^+ \) with \( F'(\eta(s_n, x)) \to 0 \) as \( n \to \infty \). By Proposition 2.1, there exists \( \hat{x} \) satisfying (1.5), (1.2).

3. Palais-Smale Sequences

In this section, we prove Proposition 2.1 and some subsidiary lemmas and propositions leading up to it. Although the full strength of Proposition 2.1 is not necessary to prove Theorem 1.1, the strong convergence of Palais-Smale sequences that it implies is interesting and may be useful for other problems. From now on we assume
\[ V(x) > 0 \text{ for all } |x| > 1, \text{ and } \lim_{|x| \to \infty} V(x) = \infty. \] (3.1)
We may make this assumption because the solution we will find to (1.5) takes values in \((-1, 1)\). Then

**Lemma 3.1.** If \( x \in W^{1,2}_0(\mathbb{R}) \) with \( F(x) < \infty \), then \( x(t) \to -1 \) or \( x(t) \to 1 \) as \( t \to -\infty \), and \( x(t) \to 1 \) or \( x(t) \to -1 \) as \( t \to \infty \). In fact, \( x + 1 \in W^{1,2}((-\infty, 0]) \) or \( x - 1 \in W^{1,2}((0, \infty)) \) if \( x + 1 \in W^{1,2}((-\infty, 0]) \) or \( x - 1 \in W^{1,2}((0, \infty)) \).

Proof: suppose the lemma is false. Then there exist \( x \in W^{1,2}_0(\mathbb{R}) \) with \( F(x) < \infty \), \( \delta > 0 \) and a sequence \((t_n)\) with \( |t_n| \to \infty \) as \( n \to \infty \)
\[ x_n(t) \in (-\infty, -1 - \delta) \cup (-1 + \delta, 1 - \delta) \cup (1 + \delta, \infty). \] (3.2)
Let
\[ d = \inf \{V(x) \mid x \in (-\infty, -1 - \delta/2) \cup (-1 + \delta/2, 1 - \delta/2) \cup (1 + \delta/2, \infty)\} > 0. \] (3.3)
Assume without loss of generality that \( t_n \to \infty \), and taking a subsequence if necessary, that \( t_{n+1} \geq t_n + 1 \) for all \( n \). If \( x(t) \in (-\infty, -1 - \delta/2) \cup (-1 + \delta/2, 1 - \delta/2) \cup (1 + \delta/2, \infty) \) for all \( t \in [t_n, t_{n+1}] \), then \( \int_{t_n}^{t_{n+1}} V(x(t)) \, dt \geq \delta \). Otherwise, there exists \( t^* \in [t_n, t_{n+1}] \) with \( |x(t_n) - x(t^*)| \geq \delta/2 \), and by the Cauchy-Schwarz inequality,

\[
\delta/2 \leq |x(t_n) - x(t^*)| \leq \int_{t_n}^{t^*} |\dot{x}(t)| \, dt \leq \sqrt{t^* - t_n} \int_{t_n}^{t^*} \dot{x}(t)^2 \, dt \leq \sqrt{\int_{t_n}^{t^*} \dot{x}(t)^2 \, dt},
\]

(3.4)

\[
\int_{t_n}^{t_n+1} \dot{x}(t)^2 \, dt \geq \int_{t_n}^{t^*} \dot{x}(t)^2 \, dt \geq \delta^2/4.
\]

Either way,

\[
\int_{t_n}^{t_n+1} \frac{1}{2} \dot{x}(t)^2 + a(t)V(x(t)) \, dt \geq \min(\delta^2/8, d_\ell),
\]

(3.6)

and

\[
F(x) \geq \sum_{n=1}^{\infty} \int_{t_n}^{t_n+1} \frac{1}{2} \dot{x}(t)^2 + a(t)V(x(t)) \, dt \geq \sum_{n=1}^{\infty} \min(\delta^2/8, d_\ell) = \infty,
\]

(3.7)

which is a contradiction. So \( x(t) \to -1 \) or \( x(t) \to 1 \) as \( t \to \infty \). Similarly, \( x(t) \to -1 \) or \( x(t) \to 1 \) as \( t \to -\infty \).

By (V7), there exists \( \epsilon > 0 \) with \( V(x) \geq \epsilon (x + 1)^2 \) for all \( x \in (-1 - \epsilon, -1 + \epsilon) \) and \( V(x) \geq \epsilon (x - 1)^2 \) for all \( x \in (1 - \epsilon, 1 + \epsilon) \). So if \( x(t) \to 1 \) as \( t \to \infty \), there exists \( T > 0 \) such that

\[
\int_{t}^{\infty} (x(s) - 1)^2 \, ds \leq \int_{T}^{\infty} V(x(t))/\epsilon \, ds \leq \frac{1}{\epsilon} \int_{T}^{\infty} a(t)V(x(t)) \, dt \leq \frac{F(x)}{\epsilon \ell} < \infty
\]

(3.8)

and \( x - 1 \in W^{1,2}([0, \infty)) \). Similar arguments apply to the cases \( x(t) \to -1 \) as \( t \to \infty \), \( x(t) \to 1 \) as \( t \to -\infty \), and \( x(t) \to -1 \) as \( t \to -\infty \).

□

Palais-Smale sequences are bounded in \( W^{1,2}_{\text{loc}}(\mathbb{R}) \):

Lemma 3.2. Let \( A, T > 0 \). There exists \( B > 0 \) such that if \( x \in W^{1,2}_{\text{loc}}(\mathbb{R}) \) with \( F(x) \leq A \), then \( ||x||_{W^{1,1}([-T, T])} \leq B \).

Proof: clearly \( \int_{-T}^{T} \dot{x}(t)^2 \, dt \leq 2A \), so it suffices to find an upper bound on \( |x| \) over \([-T, T]\). Let \( C > 0 \) such that \( V(x) > C \) for all \( |x| \geq A/2T \). Since \( \int_{-T}^{T} V(x(t)) \, dx \leq A \), there exists \( t^* \in [T, T] \) with \( V(t^*) \leq A/2T \) and \( |x(t^*)| \leq C \). For any \( s \in [-T, T] \),

\[
|x(s)| \leq |x(t^*)| + \int_{t^*}^{s} \dot{x}(t) \, dt \leq |x(t^*)| + \sqrt{|s - t^*|} \sqrt{\int_{t^*}^{s} \dot{x}(t)^2 \, dt} \leq C + \sqrt{2T} \cdot \sqrt{2A}.
\]

(3.9)

□

For \( \Omega \subset \mathbb{R} \), define

\[
F_\Omega(x) = \int_{\Omega} \frac{1}{2} \dot{x}(t)^2 + a(t)V(x(t)) \, dt.
\]

(3.10)
We have the following lemma:

**Lemma 3.3.** If $x_0, x_1 \in (-1, 1)$, $t_0 < t_1$, and $x \in W^{1,2}([t_0, t_1])$ with $x(t_0) = x_0$ and $x(t_1) = x_1$, then

$$F_{[t_0, t_1]}(x) \geq \sqrt{2l} \left| \int_{x_0}^{x_1} \sqrt{V(x)} \, dx \right|. \quad (3.11)$$

Proof: Let $\omega^*_t$ denote the unique solution in $W$ of the differential equation

$$\ddot{x}(t) = lV'(x(t)) \quad (3.12)$$

satisfying $\omega^*_t(0) = 0$. $\omega^*_t$ minimizes the functional

$$F_{\omega^*_t}(u) = \int_{-\infty}^{\infty} \frac{1}{2} \dot{u}(t)^2 + lV(u(t)) \, dt \quad (3.13)$$

over $W$. By the argument following (1.2),

$$\dot{\omega}_t^* = \sqrt{2lV(\omega^*_t(t))}. \quad (3.14)$$

Let $x_0, x_1 \in (-1, 1)$, $t_0 < t_1$, and $x \in W^{1,2}([t_0, t_1])$ with $x(t_0) = x_0$ and $x(t_1) = x_1$. Assume $x_0 < x_1$. Now

$$\int_{t_0}^{t_1} \frac{1}{2} \dot{x}(t)^2 + lV(x(t)) \, dt \geq \int_{t_0}^{t_1} \frac{1}{2} \dot{\omega}_t^*(t)^2 + lV(\omega_t^*(t)) \, dt; \quad (3.15)$$

otherwise, we could replace $\omega^*_t|_{[\omega_t^{-1}(x_0), \omega_t^{-1}(x_1)]}$ by $x|_{[t_0, t_1]}$ to obtain $\tilde{\omega} \in W$ with $F_{\tilde{\omega}} < F_{\omega^*_t}$, contradicting the optimality of $\omega^*_t$. $\tilde{\omega}$ is defined by

$$\tilde{\omega}(t) = \begin{cases} \omega_t^*(t); & t \leq \omega_t^{-1}(x_0) \\ \omega_t^{-1}(x_0) \leq t \leq \omega_t^{-1}(x_0) + t_1 - t_0 & t \geq \omega_t^{-1}(x_0) + t_1 - t_0. \end{cases} \quad (3.16)$$

Now by (3.14)-(3.15),

$$F_{[t_0, t_1]}(x) \geq \int_{t_0}^{t_1} \dot{\omega}_t^*(t)^2 \geq \int_{t_0}^{t_1} \dot{\omega}_t^*(t) \sqrt{2lV(\omega_t^*(t))} \, dt = \int_{x_0}^{x_1} \sqrt{2lV(x)} \, dt. \quad (3.17)$$

For the case $x_0 > x_1$, define $x_R$, the reversal of $x$ on $[t_0, t_1]$, by $x_R(t) = x(t_0 + t_1 - t)$. Then $x_R(t_0) = x_1$ and $x_R(t_1) = x_0$ so by the first case,

$$F_{[t_0, t_1]}(x) \geq \int_{t_0}^{t_1} \frac{1}{2} \dot{x}_R(t)^2 + lV(x_R(t)) \, dt = \int_{t_0}^{t_1} \frac{1}{2} \dot{x}_R(t)^2 + lV(x_R(t)) \, dt \geq \int_{x_0}^{x_1} \sqrt{2lV(x)} \, dt \geq \int_{x_1}^{x_0} \sqrt{2lV(x)} \, dt \quad (3.18)$$

Recall $\xi_-$ and $\xi_+$ from (1.7), and assume from now on that

$$V(x) = V(-1 + (-1 - x)) \text{ for all } x \in [-1 - (\xi_- + 1), -1], \quad V(x) = V(1 - (x - 1)) \text{ for all } x \in [1, 1 + (1 - \xi_+)]. \quad (3.19)$$

Again, we may assume this because our solution of (1.5), (1.2) will take values in $(-1, 1)$. To prove Proposition 2.1, we will use the following:
Proposition 3.4. If \((x_n) \subset W\) with \(F'(x_n) \to 0\),

\[
F(x_n) \to b < 2B + \sqrt{2l} \int_{-1}^{1} \sqrt{V(x)} \, dx, \tag{3.20}
\]

and \(x_n \to \bar{x} \in W\) locally uniformly and weakly in \(W^{1,2}([-T,T])\) for all \(T > 0\) as \(n \to \infty\), then \(\bar{x}\) solves (1.5) and \(\|x_n - \bar{x}\| \to 0\) as \(n \to \infty\).

Proof: let \((x_n)\) and \(\bar{x}\) be as in the Proposition statement. To prove \(\bar{x}\) solves (1.5), let \(\varphi \in C_0^\infty\). Then

\[
0 = \lim_{n \to \infty} F'(x_n)\varphi = \lim_{n \to \infty} \int_{-\infty}^{\infty} \dot{x}_n(t)\dot{\varphi}(t) + V'(x_n(t))\varphi(t) \, dt = \int_{-\infty}^{\infty} \dot{\bar{x}}(t)\dot{\varphi}(t) + V'(\bar{x}(t))\varphi(t) \, dt = F'(\bar{x})\varphi, \tag{3.21}
\]

and \(\bar{x}\) is a weak solution of (1.5). Next we will show that for any \(T > 0\), \(\|x_n - \bar{x}\|_{W^{1,2}([-T,T])} \to 0\) as \(n \to \infty\). Let \(T > 0\). Since \(x_n \to \bar{x}\) uniformly on \([-T,T]\),

\[
\int_{-T}^{T} (x_n(t) - \bar{x}(t))^2 \, dt \to 0 \text{ as } n \to \infty. \tag{3.22}
\]

and it suffices to prove \(\lim_{n \to \infty} \int_{-T}^{T} \dot{x}_n(t)^2 - \dot{\bar{x}}(t)^2 \, dt = 0\). Define \((u_n) \subset W^{1,2}(\mathbb{R})\) by

\[
u_n(t) = \begin{cases} 
0; & t \leq -T - 1 \\
(x_n(-T) - \bar{x}(-T))(t + T + 1); & -T - 1 \leq t \leq -T \\
x_n(t) - \bar{x}(t); & -T \leq t \leq T \\
(x_n(T) - \bar{x}(T))(-t + T + 1); & T \leq t \leq T + 1 \\
0; & t \geq T + 1 
\end{cases} \tag{3.23}
\]

Clearly, \((u_n)\) is bounded in \(W^{1,2}(\mathbb{R})\). \(u_n \to 0\) uniformly on \([-T-1, T+1]\), so

\[
0 = \lim_{n \to \infty} F'(x_n)u_n + F'(\bar{x})u_n = \lim_{n \to \infty} \int_{-T}^{T+1} a(t)V'(x_n(t))u_n(t) \, dt - \int_{-T-1}^{T} a(t)V'(\bar{x}(t))u_n(t) \, dt = \lim_{n \to \infty} \int_{-T}^{T+1} a(t)V'(x_n(t))u_n(t) \, dt - \int_{-T-1}^{T} a(t)V'(\bar{x}(t))u_n(t) \, dt = \lim_{n \to \infty} \int_{-T}^{T+1} a(t)V'(x_n(t))u_n(t) \, dt - \int_{-T-1}^{T} a(t)V'(\bar{x}(t))u_n(t) \, dt. \tag{3.24}
\]
Since \( \|u_n\|_{W^{1,2}([-T-1,-T])} \to 0 \) and \( \|u_n\|_{W^{1,2}([T,T+1])} \to 0 \) as \( n \to \infty \),
\[
0 = \lim_{n \to \infty} (x_n, u_n)_{W^{1,2}([-T,T])} + (\bar{x}, u_n)_{W^{1,2}([-T,T])} = \\
= \lim_{n \to \infty} \int_{-T}^{T} \dot{x}_n(t)(\dot{x}_n(t) - \dot{\bar{x}}(t)) + x_n(t)(x_n(t) - \bar{x}(t)) + \dot{\bar{x}}(t)(\dot{x}_n(t) - \dot{\bar{x}}(t)) + \bar{x}(t)(x_n(t) - \bar{x}(t)) \, dt = \\
= \lim_{n \to \infty} \int_{-T}^{T} \dot{x}_n^2(t) - \dot{\bar{x}}^2(t) + x_n(t)^2 - \bar{x}(t)^2 \, dt = \lim_{n \to \infty} \int_{-T}^{T} \dot{x}_n^2(t) - \dot{\bar{x}}^2(t) \, dt.
\]
(3.25)

Therefore \( \|x_n - \bar{x}\|_{W^{1,2}([-T,T])} \to 0 \) as \( n \to \infty \).

Suppose \( \|x_n - \bar{x}\| \neq 0 \) as \( n \to \infty \). Then there exist \( \delta > 0 \) and a sequence \((T_n)\) with \( T_n \to \infty \) and
\[
\|x_n - \bar{x}\|_{\mathbb{R}\setminus[-T_n,T_n]} \geq 4\delta^2
\]
for all \( n \). Along a subsequence, either
\[
\|x_n - \bar{x}\|_{W^{1,2}((-\infty,-T_n])} \geq 2\delta^2 \text{ or } \|x_n - \bar{x}\|_{W^{1,2}([T_n,\infty))} \geq 2\delta^2.
\]
(3.27)

Let us assume the former; the latter case is similar. Since \( 1 + \bar{x} \in W^{1,2}((-\infty,0]) \),
\[
\|x_n + 1\|_{W^{1,2}((-\infty,-T_n])} \geq \delta
\]
(3.28)

for large \( n \). There are two cases to consider:

Case I: For all \( \epsilon > 0 \), there exists \( M > 0 \) such that
\[
|1 + x_n(t)| < \epsilon \text{ for all } n \text{ and } t \leq -M.
\]
(3.29)

Case II: There exists \( d \in (0,1) \) and a sequence \((t_n) \subset \mathbb{R}\) with
\[
t_n \to -\infty \text{ and } |1 + x_n(t_n)| > d \text{ for all } n.
\]

Case I: let \( \xi^* \in (-1,\xi_-) \) and \( c \in (0,1) \) such that
\[
V'(x) x \geq c(1 + x)^2
\]
(3.30)

for all \( x \in [-1-(\xi^*+1),\xi^*] \). This is possible by \( (V_3)-(V_5) \), (3.19), and the definition of \( \xi_- \). Let \( M > 0 \) be large enough so that
\[
|1 + x_n(t)| < \min\{1 + \xi^*, -\frac{c\delta^2}{8(1 + \sqrt{b})}\}
\]
(3.31)

for all \( n \in \mathbb{N} \), \( t \leq -M \). Define \((u_n) \subset W^{1,2}(\mathbb{R})\) by
\[
u_n(t) = \begin{cases}
1 + x_n(t); & t \leq -M \\
(1 + x_n(-M))(1 - M - t); & -M \leq t \leq -M + 1 \\
0; & t \geq -M + 1
\end{cases}
\]
(3.32)

We will show \((u_n)\) is uniformly bounded in \( W^{1,2}(\mathbb{R}) \). Let \( K > 0 \) so
\[
|V'(x)| \leq K \text{ and } (x + 1)^2 \leq KV(x)
\]
(3.33)
for all \( x \in [-1 - (\xi + 1), \xi] \). This is possible by \((V_1)-(V_2),(3.19)\), and the definition of \( \xi_- \). For large \( n \),

\[
\| u_n \|^2 = \int_{-\infty}^{-M} \dot{x}_n(t)^2 + (1 + x_n(t))^2 \, dt + (1 + x_n(-M))^2 + \frac{1}{2} (1 + x_n(-M)) \leq
\]

\[
\leq (2 + \frac{K}{l}) \int_{-\infty}^{-M} \frac{1}{2} \dot{x}_n(t)^2 + a(t)V(x_n(t)) \, dt +
\]

\[
+ (1 + \bar{x}(-M))^2 + \frac{1}{2} (1 + \bar{x}(-M)) + 1 \leq
\]

\[
\leq (2 + \frac{K}{l}) F(x_n) + (1 + \bar{x}(-M))^2 + \frac{1}{2} (1 + \bar{x}(-M)) + 1 \leq
\]

\[
\leq (2 + \frac{K}{l})(2b) + (1 + \bar{x}(-M))^2 + \frac{1}{2} (1 + \bar{x}(-M)) + 1.
\]

(3.34)

\( F'(x_n) \to 0 \), so \( F'(x_n)u_n \to 0 \) as \( n \to \infty \). But for large \( n \),

\[
F'(x_n)u_n = \int_{-\infty}^{-M} \dot{x}_n(t)^2 + V'(x_n(t))(1 + x_n(t)) \, dt +
\]

\[
+ \int_{-M}^{-M+1} (1 + x_n(-M)) \dot{x}_n(t) \, dt +
\]

\[
+ \int_{-M}^{-M+1} (1 + x_n(-M))(1 - M - t) \, dt \geq
\]

\[
\geq \int_{-\infty}^{-M} \dot{x}_n(t)^2 + c(1 + x_n(t))^2 \, dt - |1 + x_n(-M)| \sqrt{\int_{-M}^{-M+1} \dot{x}_n(t)^2 \, dt -
\]

\[
\frac{1}{2} |1 + x_n(-M)| \geq
\]

\[
\geq c\|1 + x_n\|_{W^{1,2}(-\infty, -M)} - |1 + x_n(-M)|({\sqrt{2F(x_n)} + 1}) \geq
\]

\[
\geq c\delta^2 - (1 + 2\sqrt{b}) |1 + x_n(-M)| \geq \frac{1}{2}c\delta^2
\]

(3.35)

by (3.31). This is impossible.

Case II: by the arguments of Lemma 3.3,

\[
F(x) \geq \sqrt{2l} \int_{-1}^{1} \sqrt{V(x)} \, dx
\]

(3.36)

for all \( x \in W \), including \( \bar{x} \). Let \( d \) and \((t_n)\) be as in (3.29). Let \( M > 0 \) be large enough so that \( |1 + \bar{x}(t)| < d/2 \) for all \( t \leq -M \), and

\[
F_{[-M,M]}(\bar{x}) > \sqrt{2l} \int_{-1}^{1} \sqrt{V(x)} \, dx - \frac{1}{10} (2B + \sqrt{2l} \int_{-1}^{1} \sqrt{V(x)} \, dx - b).
\]

(3.37)

Define \( \alpha_n \leq \beta_n < -M \) by

\[
\beta_n = \max\{t < -M \mid |1 + x_n(t)| = d\}, \quad \alpha_n = \min\{t \mid |1 + x_n(t)| = d\}
\]

(3.38)

Since \( x_n \to \bar{x} \) locally uniformly and \( |1 + \bar{x}(t)| < d/2 < 1 \) for all \( t \leq -M \), \( \beta_n \to -\infty \) as \( n \to \infty \). Define \( v_n = \tau_{-\beta_n}x_n \). By Fatou’s Lemma, the weak lower semicontinuity
of $\int_{-\infty}^{\infty} \dot{x}(t)^2 dt$, and Lemma 3.2, there exists $\bar{v} \in W^{1,2}(\mathbb{R})$ with $F(\bar{v}) < \infty$ and $v_n \to \bar{v}$ locally uniformly and weakly in $W^{1,2}([-T,T])$ for all $T > 0$. By the arguments of (3.21), $F'(\bar{v}) = 0$. By the definition of $\beta_n$, $\bar{v}(t) \leq -1 + d < 0$ for all $t > 0$. Therefore, by the arguments of Lemma 3.1 applied to $F_1$ instead of $F$, $\bar{v}(t) \to -1$ as $t \to \infty$. By the arguments following (1.2), $\dot{\bar{v}}(t) = -\sqrt{2V(\bar{v}(t))}$ for all $t \in \mathbb{R}$. Let $\omega_R$ denote the reversal of $\omega$: $\omega_R(t) = \omega(-t)$ for all $t$. $\bar{v} = \tau_\lambda \omega_R$ for some $\lambda \in \mathbb{R}$. By the arguments of (3.22)-(3.25),

\[
\|x_n - \tau_{\lambda + \beta_n} \omega_R\|_{W^{1,2}([\beta_n - T, \beta_n + T])} \to 0 \quad (3.39)
\]

as $n \to \infty$ for all $T > 0$. This implies $\beta_n - \alpha_n \to \infty$ as $n \to \infty$. For all $n$ and all $t < \alpha_n$, $x_n(t) < -1 + d/2 < 0$. Therefore, arguments similar to those above show that there exists $\lambda_2 \in \mathbb{R}$ with

\[
\|x_n - \tau_{\lambda_2 + \alpha_n} \omega\|_{W^{1,2}([\alpha_n - T, \alpha_n + T])} \to 0 \quad (3.40)
\]

for all $T > 0$ as $n \to \infty$. For $\Omega \subset \mathbb{R}$, define

\[
F_{\Omega}(x) = \int_{\Omega} \frac{1}{2} \dot{x}(t)^2 + lV(x(t)) \, dt \quad (3.41)
\]

Still assuming that $M$ is large enough so that (3.37) holds, assume also that $M$ is large enough that

\[
F_{[-M,M]}(\tau_{\lambda \omega_R}) > B - \frac{1}{10} (2B + \sqrt{2l} \int_{-1}^{1} \sqrt{V(x)} \, dx - b),
\]

\[
F_{[-M,M]}(\tau_{\lambda_2 \omega}) > B - \frac{1}{10} (2B + \sqrt{2l} \int_{-1}^{1} \sqrt{V(x)} \, dx - b), \quad (3.42)
\]

Then for large $n$, (3.37), (3.39)-(3.42), $\alpha_n \to -\infty$, $\beta_n \to -\infty$, and $a(t) \to t$ as $|t| \to \infty$ imply

\[
F(x_n) \geq F_{[\alpha_n - M, \alpha_n + M]}(x_n) + F_{[\beta_n - M, \beta_n + M]}(x_n) + F_{[-M,M]}(x_n) \geq
\]

\[
\geq (B - \frac{1}{5} (2B + \sqrt{2l} \int_{-1}^{1} \sqrt{V(x)} \, dx - b)) +
\]

\[
+ (B - \frac{1}{5} (2B + \sqrt{2l} \int_{-1}^{1} \sqrt{V(x)} \, dx - b)) +
\]

\[
+ (\sqrt{2l} \int_{-1}^{1} \sqrt{V(x)} \, dx - \frac{1}{5} (2B + \sqrt{2l} \int_{-1}^{1} \sqrt{V(x)} \, dx - b)) -
\]

\[
\geq \frac{1}{5} (2B + \sqrt{2l} \int_{-1}^{1} \sqrt{V(x)} \, dx - b) =
\]

\[
= 2B + \sqrt{2l} \int_{-1}^{1} \sqrt{V(x)} \, dx - \frac{4}{5} (2B + \sqrt{2l} \int_{-1}^{1} \sqrt{V(x)} \, dx - b) \equiv b^+ > b. \quad (3.43)
\]

This is impossible. Proposition 3.4 is proven. \qed

Proof of Proposition 2.1 There are two cases: $b < B$ and $b > B$. The case $b < B$ is easier. Let $(x_n) \subset W$ with $F(x_n) \to b < B$ and $F'(x_n) \to 0$ as $n \to \infty$. By Lemma 3.2, $(x_n)$ converges locally uniformly and weakly in $W^{1,2}([-T,T])$ for all $T > 0$ to some function $\bar{x} \in W^{1,2}_{loc}(\mathbb{R})$. By Fatou’s Lemma and the weak lower semicontinuity of $\int_{-\infty}^{\infty} \dot{x}(t)^2 dt$, $F(\bar{x}) < \infty$. By Proposition 3.4, it suffices to show
Let $\bar{x} \notin W$. Suppose $\bar{x} \notin W$. Then by Lemma 3.1, $\bar{x}(t) \to 1$ as $t \to -\infty$ or $\bar{x}(t) \to -1$ as $t \to \infty$. Suppose $\bar{x}(t) \to -1$ as $t \to \infty$ (the proof for $\bar{x}(t) \to 1$ as $t \to -\infty$ is similar). Define
\[
B_\epsilon = \int_{\omega^{-1}(1-\epsilon)}^{\omega^{-1}(-1+\epsilon)} \frac{1}{2} \omega^2(t) + lV(\omega(t)) \, dt
\] (3.44)
for $\epsilon > 0$. Let $\epsilon > 0$ be small enough that
\[
\left( \frac{l - \epsilon}{l} \right) B_\epsilon > b.
\] (3.45)
Let $T > 0$ be large enough so that $a \geq l - \epsilon$ on $[T, \infty)$ and $\bar{x}(T) < -1 + \epsilon$. Let $n$ be large enough that $x_n(T) < -1 + \epsilon$. Let $T < \alpha < \beta$ with $x_n(\alpha) = -1 + \epsilon$, $x_n(\beta) = 1 - \epsilon$. By arguments similar to those of Lemma 3.3,
\[
F(x_n) \geq F_{[\alpha, \beta]}(x_n) = \int_{\alpha}^{\beta} \frac{1}{2} \dot{x}_n(t)^2 + a(t)V(x_n(t)) \, dt \geq
\geq \int_{\alpha}^{\beta} \frac{1}{2} \dot{x}_n(t)^2 + (l - \epsilon)V(x_n(t)) \, dt \geq
\geq \frac{l - \epsilon}{l} \int_{\alpha}^{\beta} \frac{1}{2} \dot{x}_n(t)^2 + lV(x_n(t)) \, dt \geq
\geq \frac{l - \epsilon}{l} B_\epsilon \equiv b^+ > b.
\] (3.46)
This is a contradiction.

Now suppose $b \in (B, B + 2\nu \sqrt{\beta})$. As before, along a subsequence, $(x_n)$ converges locally uniformly and weakly in $W^{1,2}([-T, T])$ for all $T > 0$ to a function $\tilde{x} \in W^{1,2}_{loc}(\mathbb{R})$ with $F(\tilde{x}) \leq b$. We must show $\tilde{x} \in W$; then applying Proposition 3.4 proves Theorem 1.1. Suppose $\tilde{x}(t) \neq 1$ as $t \to \infty$ (the proof for $\tilde{x}(t) \neq -1$ as $t \to -\infty$ is similar). By Lemma 3.1, $\bar{x}(t) \to -1$ as $t \to \infty$. Let $t_n = \max\{t \mid x_n(t) = 0\}$. Then $t_n \to \infty$ as $n \to \infty$. By the arguments following (3.38) and the arguments of (3.22)-(3.25),
\[
\|x_n - \tau_n \omega\|_{W^{1,2}([-T_n - M, T_n + M])} \to 0
\] (3.47)
as $n \to \infty$ for all $M > 0$. Let $-1 < e_1 < \xi_1 < \xi_-$ with
\[
\sqrt{2l} \int_{e_1}^{\xi_1} \sqrt{V(x)} \, dx > \nu \sqrt{2l} - \frac{1}{6} (B + 2\nu \sqrt{2l} - b).
\] (3.48)
Let $c \in (0, 1)$ with
\[
V'(x)(1 + x) \geq cV(x)
\] (3.49)
for all $x \in [-1, \xi_1]$. Let $K > 0$ be large enough that
\[
|V'(x)| < K
\] (3.50)
for all $x \in [-1, 1]$. Let $M > 0$ be large enough that
\[
F_{[-M, M]}(\omega) > B - \frac{1}{6} (B + 2\nu \sqrt{2l} - b)
\] (3.51)
and
\[
1 + \omega(-M) < \min\left( \frac{c(b - B)}{16(K + 2\sqrt{b})}, 1 + e_1 \right).
\] (3.52)
By (3.47) and the fact that $a(t) \to l$ as $t \to \infty$,

$$F_{[t_n-M,t_n+M]}(x_n) < \mathcal{B} + \frac{1}{2}(b - \mathcal{B})$$

(3.53)

for large $n$, so

$$F_{(-\infty,t_n-M]}(x_n) + F_{[t_n+M,\infty)}(x_n) > \frac{1}{3}(b - \mathcal{B}).$$

(3.54)

Assume $F_{(-\infty,t_n-M]} > (b - \mathcal{B})/6$ (the case $F_{[t_n+M,\infty)} > (b - \mathcal{B})/6$ is similar). There are two possible cases: along a subsequence,

Case I: $|1 + x_n(\alpha_n)| \geq 1 + \xi_1$ for $\alpha_n < t_n - M$,
Case II: $|1 + x_n(t)| < 1 + \xi_1$ for all $t < t_n - M$.

(3.55)

For Case I, assume $1 + x_n(\alpha_n) \geq 1 + \xi_1$ (the case $1 + x_n(\alpha_n) \leq -(1 + \xi_1)$ is similar due to (3.19)). For large $n$, by Lemma 3.3, (3.48), (3.52), (3.47), (3.51), $(A_1)$, and $t_n \to \infty$,

$$F(x_n) \geq F_{(-\infty,\alpha_n]}(x_n) + F_{[\alpha_n,t_n-M]}(x_n) + F_{[t_n-M,t_n+M]}(x_n) \geq$$

$$\geq 2(\nu \sqrt{2l} - \frac{1}{5}(B + 2\nu \sqrt{2l} - b)) + (B - \frac{1}{5}(B + 2\nu \sqrt{2l} - b)) =$$

$$= B + 2\nu \sqrt{2l} - \frac{3}{5}(B + 2\nu \sqrt{2l} - b) \equiv b^+ > b.$$ 

(3.56)

This is impossible. For Case II, define $(u_n) \subset W^{1,2}(\mathbb{R})$ by

$$u_n(t) = \begin{cases} 
1 + x_n(t); & t \leq t_n - M \\
(1 + x_n(t_n - M))(t_n - M + 1 - t); & t_n - M \leq t \leq t_n - M + 1 \\
0; & t \geq t_n - M + 1
\end{cases}$$

(3.57)
(u_n) is uniformly bounded in $W^{1,2}(\mathbb{R})$, as in (3.34). So $F'(x_n)u_n \to 0$. But for large $n$,
\[
F'(x_n)u_n = \int_{-\infty}^{t_n-M} \dot{x}_n(t)^2 + a(t)V'(x_n(t))(1 + x_n(t)) \, dt - (1 + x_n(t_n - M)) \int_{t_n-M}^{t_n-M+1} \dot{x}_n(t) \, dt + (1 + x_n(t_n - M)) \int_{t_n-M}^{t_n-M+1} V'(x_n(t))(t_n - M + 1 - t) \, dt \geq \\
\int_{-\infty}^{t_n-M} \dot{x}_n(t)^2 + ca(t)V(x_n(t)) \, dt - |1 + x_n(t_n - M)| \sqrt{\int_{t_n-M}^{t_n-M+1} \dot{x}_n(t)^2 \, dt} - K|1 + x_n(t - M)| = cF_{(-\infty, t_n-M]}(x_n) - (K + 2\sqrt{b})|1 + x_n(t_n - M)| \geq \\
\geq \frac{1}{6} c(b - B) - \frac{1}{12} c(b - B) = \frac{1}{12} c(b - B) > 0
\]
by (3.52). This is impossible. Case II is proven. Proposition 2.1 is proven.

\[\square\]

4. Completion of Proof

In this section we tie up some loose ends from Section 2. It was asserted that $c < \mathcal{B} + 2\nu\sqrt{2\mathcal{I}}$, where $c$ is from (2.8). Define $\gamma_0 \in \Gamma$ by $\gamma_0(t) = \tau_0(\omega)$. We will show $\sup_{t \in \mathbb{R}} F(\omega_0(t)) < \mathcal{B}$. Since $F(\gamma_0(t)) \to \mathcal{B}$ as $|t| \to \infty$, and $F(\gamma_0(t))$ is continuous in $t$, it suffices to prove that $F(\gamma_0(t)) < \mathcal{B} + 2\nu\sqrt{2\mathcal{I}}$ for all $t \in \mathbb{R}$. We will prove this for $t = 0$; the proof is similar for other $t$. After (1.2), it is proven that
\[
V(\omega(t)) = \frac{\dot{\omega}(t)}{\sqrt{2l}} \sqrt{V(\omega(t))}
\]
for all $t$. Since $a(t) \to l$ as $|t| \to \infty$, and $\omega(t) \in (-1, 1)$ for all $t$, (A2) gives us
\[
F(\gamma_0(0)) = F(\omega) = \int_{-\infty}^{\infty} \frac{1}{2} \dot{\omega}(t)^2 + a(t)V(\omega(t)) \, dt < \\
< \int_{-\infty}^{\infty} \frac{1}{2} \dot{\omega}(t)^2 + LV(\omega(t)) \, dt = \\
= \int_{-\infty}^{\infty} \frac{1}{2} \dot{\omega}(t)^2 + lV(\omega(t)) \, dt + (L - l) \int_{-\infty}^{\infty} V(\omega(t)) \, dt = \\
= \mathcal{B} + \frac{4\nu\sqrt{\mathcal{I}}}{\int_{-1}^{1} \sqrt{V(x)} \, dx} \int_{-\infty}^{\infty} \frac{1}{\sqrt{2l}} \dot{\omega}(t) \sqrt{V(\omega(t))} \, dt = \mathcal{B} + 2\nu\sqrt{2\mathcal{I}}
\]
We must prove that the gradient vector flow from (2.11) is well-defined on \( \mathbb{R}^+ \times W \). Since \( F \) is \( C^2 \), it suffices to show that for all \( A > 0 \), there exists \( B > 0 \) such that if \( x \in W \) with \( F(x) \leq A \), \( ||F'(x)|| \leq B \): By (V2), it is possible to extend V from \([-1 - (\xi_+ - 1), 1 + (1 - \xi_-)]\) to \( \mathbb{R} \) such that there exists \( K > 0 \) with \( V'(x)^2 \leq KV(x) \) for all real \( x \). Let \( x \in W \) with \( F(x) \leq A \) and \( u \in W^{1,2}(\mathbb{R}) \) with \( ||u||_{W^{1,2}(\mathbb{R})} = 1 \). Then

\[
F'(x)u = \int_{-\infty}^{\infty} \dot{x}(t)u(t) + a(t)V'(x(t))u(t) \, dt \leq \sqrt{2A + L} \int_{-\infty}^{\infty} K \left( \frac{1}{t} \int_{-\infty}^{\infty} a(t)V(x(t)) \, dt \right) \leq \sqrt{2A + L} \int_{-\infty}^{\infty} \frac{KA}{T}.
\]

(4.3)

Here is the “standard deformation argument” alluded to after (2.8): suppose \( c > B \), and suppose there does not exist a Palais-Smale sequence \( (x_n) \subset W \) with \( F(x_n) \rightarrow c \) and \( F'(x_n) \rightarrow 0 \). Then there exist \( \epsilon, \delta > 0 \) such that \( ||F'(x_n)|| > \delta \) for all \( x \in W \) with \( F(x) \in [c - \epsilon, c + \epsilon] \). Let \( \gamma \in \Gamma \) with \( \sup_{t \in \mathbb{R}} F(\gamma(t)) < c + \epsilon \). Let \( T > 0 \) be large enough so that \( F(\gamma(t)) < c \) (\( > B \)) for \( |t| \geq T \). Let \( \varphi \in C(\mathbb{R}, [0,1]) \) with \( \varphi = 0 \) on \((-\infty, -T - 1] \cup [T + 1, \infty) \) and \( \varphi = 1 \) on \([-T, T] \). Define \( \gamma_2 \in \Gamma \) by \( \gamma_2(t) = \eta(t) \gamma(t) \), where \( \eta \) is the gradient vector flow from (2.11). Since \( \frac{d}{dt} F(\eta(s, u)) = -||F'(\eta(s, u))||^2 \) for all \( u \in W \), \( s \in \mathbb{R}^+ \), \( F(\gamma_2(t)) < c \) for all \( t \in \mathbb{R} \). \( F(\gamma_2(t)) \rightarrow B \) as \( |t| \rightarrow \infty \), so \( \sup_{t \in \mathbb{R}} F(\gamma_2(t)) < c \), contradicting the definition of \( c \).

In the case \( c = B \) after (2.8), we have \( (x_n) \subset W \) with \( F(x_n) \rightarrow B \) as \( n \rightarrow \infty \) and \( x_n(0) = 0 \) for all \( n \). Since \( F(x_n) \) is bounded, there exists \( \bar{x} \in W_{loc}^{1,2}(\mathbb{R}) \) and a subsequence of \( (x_n) \) (also denoted \( x_n \)) such that \( x_n \rightarrow \bar{x} \) locally uniformly and weakly in \( W^{1,2}([-T, T]) \) for all \( T > 0 \). As before, \( F(\bar{x}) \leq B \). We must prove \( \bar{x} \in W \). Suppose otherwise. By Lemma 3.1, \( \bar{x}(t) \rightarrow 1 \) or \(-1 \) as \( t \rightarrow \infty \) and \( \bar{x}(t) \rightarrow 1 \) or \(-1 \) as \( t \rightarrow -\infty \). Suppose \( \bar{x}(t) \rightarrow -1 \) as \( t \rightarrow \infty \) (the proof for \( \bar{x}(t) \rightarrow 1 \) as \( t \rightarrow -\infty \) is similar). Let \( B_\epsilon \) be as in (3.44) and let \( \epsilon > 0 \) be small enough that

\[
\frac{l - \epsilon}{l} B_\epsilon > B - F_{[-1,1]}(\bar{x})/2.
\]

(4.4)

Let \( T > 1 \) be large enough so \( a \geq l - \epsilon \) on \([t, \infty) \) and \( \bar{x}(T) < -1 + \epsilon \). Then, as in (3.46), for large \( n \),

\[
F(x_n) \geq F_{[-1,1]}(x_n) + F_{[T, \infty]}(x_n) \geq F_{[-1,1]}(\bar{x})/2 + \frac{l - \epsilon}{l} B_\epsilon > B.
\]

(4.5)

This is impossible.

The final step in the proof is to show that a solution of (1.1) in \( W \) takes values in \((-1, 1) \). Suppose \( x \in W \) and solves (1.1). If \( x(t) > 1 \) for some real \( t \), then let \( t_{\max} \in \mathbb{R} \) with \( x(t_{\max}) = \max_{t \in \mathbb{R}} x(t) \). \( \dot{x}(t_{\max}) \leq 0 \), but \( V(x(t_{\max})) > 0 \). This
is impossible. Similarly, $x(t) \leq 1$ for all real $t$. Now suppose $x(t^*) = 1$. Then $x$ satisfies the Cauchy problem (1.1), $x(t^*) = 1$, $\dot{x}(t^*) = 0$, so by $(V_1)$, $x \equiv 1$. This is a contradiction. Similarly, $x(t) > -1$ for all real $t$.
