Abstract: Though individuals prefer to join groups with high quality peers, there are advantages to being high up in the pecking order within a group if higher ranked members of a group have greater access to the group’s resources. When two organizations try to attract members from a fixed population of heterogeneous agents, how resources are distributed among the members according to their rank affects how agents choose between the organizations. Competition between the two organizations has implications for both the equilibrium sorting of agents and the way resources are distributed within each organization. To compete more intensely for the more talented agents, both organizations are selective and give no resources to their low ranks. In both organizations, higher ranks are rewarded with more resources, with a greater rate of increase in the organization that has a lower average quality in equilibrium.

Acknowledgments: We thank Dirk Bergemann, Simon Board, Jeff Ely, Mike Peters, and seminar audience at University of British Columbia, University of Toronto, University of Western Ontario and Yale University for helpful comments and suggestions.
1. Introduction

Distributions of talents across organizations exhibit patterns of both mixing and segregation. At the risk of being accused of self-indulgence, let us look at the example of distribution of economists by productivities across departments. Highly productive researchers can be found in many second-tier departments as well as in top-ranked institutions. However, there is an unmistakable hierarchy of departments in terms of average productivity of their faculty members.

A plausible explanation for the coexistence of mixing and segregation is sorting by talents who care both about the quality of the institution they join and about their relative ranking within the institution. In Damiano, Li and Suen (2005), we call these two concerns “peer effect” and “pecking order effect.” The peer effect is widely acknowledged in the education literature (e.g., Coleman et al., 1966; Summers and Wolfe, 1977; Lazear, 2001; Sacerdote 2001), and modeled extensively in the literature on locational choice (De Bartolome, 1990; Eppe and Romano, 1998). The pecking order effect can be motivated by concerns for self-esteem (Frank, 1985), competition for mates in the same location (Cole, Mailath and Postlewaite, 1992), or competition for resources among members of an organization (Postlewaite, 1998). These two effects highlight competition and cooperation as two important features of the interaction among talents within an organization.

This paper studies organizational strategies to attract talents in the presence of these concerns, and analyzes the resulting equilibrium pattern of sorting. Consider an academic department trying to improve its standing by hiring a new faculty member. Several economic forces influence such a decision. First, if the potential appointee is of high quality, the presence of such a colleague in the department will make the department more attractive to other faculty members and may therefore help the department’s other recruiting efforts. Second, the new recruit can upset the department’s existing hierarchical structure and bring about implications for the internal distribution of departmental resources. “Salary inversion” is often seen as a potential problem in academia (Lamb and Moates, 1999; Siegfried and Stock, 2004). More generally, conventional wisdom in personnel management emphasizes the importance of “internal relativity” in the reward structure of any
organization. In other words, the decision to make a job offer cannot be viewed in isolation; instead the entire reward structure of the organization has to be taken into account. Third, in a thin labor market with relatively few employers, the recruitment efforts of one department will affect the availability of the labor pool for another department. Hiring decisions therefore have general equilibrium repercussions that needs to be taken into account.

Our paper develops a model of the competition for talents which incorporates all these economic forces.\(^1\) In our model, talents care about their relative ranking within the organization they join because higher ranks receive more resources, and they care about the overall quality of the organization. Organizations compete for talents by designing how resources are allocated according to rank. We characterize a unique equilibrium of organizational competition which determines the entire reward structure of each organization, as well as the equilibrium pattern of sorting. In equilibrium the targets of competition are the top talents; only these agents receive positive shares of resources from either organization. Furthermore, equilibrium reward structures are systematically different between the high quality organization and the low quality organization. The organization that in equilibrium attracts a higher average quality of talents has a more egalitarian distribution of resources than the low quality organization, because the low quality organization is disadvantaged by the peer effect and must concentrate its resources on a smaller set of top talents. The equilibrium sorting of talents exhibits mixing of top talents, with a greater share of them going to the high quality organization, while segregation occurs for all types that receive no resources in equilibrium, with the better types going to the high quality organization.

In section 2, we formally introduce our model of organizational competition. The model is broadly based on Damiano, Li and Suen (2005). Talents have one-dimensional types distributed uniformly, and a utility function linear in the average type of the organization they join and the resource they receive in the organization. Each organization faces a fixed capacity constraint that allows it to accept half of an exogenously given talent pool.

\(^1\) The existing economic literature on the competition for talents typically focuses on either the informational spillovers resulting from offers and counter-offers (Bernhardt and Scoones, 1993; Lazear, 1996), or the implications of raiding for firms’ incentive to offer training (Moen and Rosen, 2004). Tranaes (2001) studies the impact of raiding opportunities on unemployment in a search environment.
and a fixed total budget of resources that can be allocated among its ranks. We use the notion of sorting equilibrium defined in Damiano, Li and Suen (2005) to describe how talents sort after the organizations have chosen their resource distribution schedules. The issue of multiple equilibria is resolved by labeling the organization with a greater resource budget (or either of the two organizations when they have the same budget) as the “dominant” one, and selecting the sorting equilibrium with the largest difference in average types in its favor. This quality difference then defines the payoffs of the two organizations in the game in which they simultaneously choose their resource distribution schedules.

The game of organizational competition is strictly competitive. In section 3, we show that the game has a minmax value corresponding to the largest quality difference that the dominant organization can obtain in a Nash equilibrium of the game. The technical difficulty in this step lies in the fact that we do not have a characterization of the selected sorting equilibrium in terms of an arbitrary pair of resource distribution schedules, so we cannot use the standard approach of constructing best response correspondences. Instead, under the assumption that the type distribution is uniform, we transform the minmax problem into one in which the weaker organization maximizes the minimum resource budget required to achieve a given target of quality difference. We then use the result to characterize the minmax value and identify a unique resource distribution schedule for the weaker organization to achieve the value. There is a critical rank that receives strictly positive resource, with all ranks below receiving no resources and the resources received by the ranks above increasing linearly in rank. Intuitively, the weaker organization has to pay a peer effect premium in order to compete with the dominant organization, which leads to the jump in the resource distribution schedule at the critical rank. Further, a linear resource allocation schedule is necessary in order to avoid having its high ranks cherry-picked by the rival organization.

In section 4 we characterize a unique Nash equilibrium of the organizational competition. The existence of the equilibrium is established by construction. In equilibrium the dominant organization chooses a resource distribution schedule similar to the minmax schedule of the weaker organization. There is a critical rank below which ranks receive no resources in the dominant organization, because they attract no competition from the
weaker organization. Ranks above the critical rank in the dominant organization receive resources that increase linearly in rank, with no discontinuity at the critical rank and a smaller rate of increase than that in weaker organization. Sorting of talents in this equilibrium involves mixing of top talents between the two organizations, and segregation for low types. We also show that the equilibrium is a unique one, by establishing that for any other resource distribution schedule of the dominant organization, the weaker organization can improve upon the minmax schedule.

Section 5 provides some comparative statics results regarding the unique Nash equilibrium of the game of competing for talents. When the organizations have a greater budget for resource distribution, or when the peer effect becomes less important in the talents’ utility function, the equilibrium exhibits a smaller disparity between the dominant and the weaker organizations. We then conclude the paper in section 6 with brief discussions of some of the main assumptions of the model.

2. The Model

Two organizations, A and B, compete for a measure 2 of agents. Agents differ with respect to a one-dimensional continuously distributed characteristic, called “type” and denoted by $\theta$. We assume that the distribution of $\theta$ is uniform on the interval $[0, 1]$. Each organization $i = A, B$ has a measure 1 of positions and a fixed resource budget $Y_i$ to be allocated among its members. Without loss of generality, we assume that $Y_A \geq Y_B$. An organization determines the distribution of its resource budget $Y_i$ by choosing a “resource distribution schedule.” A resource distribution schedule for organization $i$ is a function $S_i : [0, 1] \rightarrow \mathbb{R}_+$, which stipulates how $Y_i$ is allocated among $i$’s members according to their rank. For each $r \in [0, 1]$, let $S_i(r)$ denote the amount of resources received by an agent of type $\theta$ when a fraction $r$ of the organization’s members are of type smaller than $\theta$. We make the assumption that organizations can only adopt “meritocratic” resource distribution schedules in which members of higher ranks receive at least as much resources as lower ranks. We also make the technical assumption that only resource distribution schedules which are almost everywhere continuously differentiable are admissible. Each
organization must fill all its positions and each wants to maximize its own quality, measured by the average type of its members.

Preferences of agents over the two organizations depend on the comparison of the qualities of the two organizations and of the amount of resources they receive when joining. For each \( i = A, B \), let \( m_i \) be the average type of agents in organization \( i \). Let \( r_i(\theta) \) be the quantile rank of an agent of type \( \theta \) in organization \( i \). If \( S_i \) is the resource distribution schedule in organization \( i \), then the utility to an agent \( \theta \) from joining organization \( i \) is given by

\[
V_i(\theta) = \alpha S_i(r_i(\theta)) + m_i
\]

where \( \alpha \) is a positive constant that represents the weight on the concern for the pecking order effect relative to the concern for the peer effect.\(^2\) The payoff is zero if an agent does not join either organization.

### 2.1. Sorting equilibrium

Since each agent’s outside option is zero and each organization must fill all positions, a feasible allocation of the agents among the two organizations can be described by a pair of the type distribution functions in the two organizations, as follows.

**Definition 2.1.** A feasible allocation is a pair of cumulative distribution functions \((H_A, H_B)\) such that \( H_A(\theta) + H_B(\theta) = 2\theta \) for all \( \theta \in [0, 1] \).

Given a pair of resource distribution schedules \((S_A, S_B)\), the agents sort themselves between the two organizations. We call this the sorting stage. We adapt the notion of “priority equilibrium” in Damiano, Li and Suen (2005) to the present environment.

**Definition 2.2.** Given a pair of resource distribution schedules \((S_A, S_B)\), a sorting equilibrium is a feasible allocation \((H_A, H_B)\) such that if \( H_i \) is strictly increasing on \((\theta, \theta')\) and \( H_j(\theta) > 0 \), then \( V_i(\theta) \geq V_j(\theta) \).

---

\(^2\) In our model agents do not directly care about their relative ranking in the organization. The concern for the pecking order effect is generated endogenously because the organizations choose how to distribute resources according to ranks.
The notion of sorting equilibrium above suggests that an agent will join organization $i$ whenever he prefers organization $i$ and his type is higher than the lowest type of the other organization.$^3$

Existence of a sorting equilibrium can be established by a fixed point argument. Before doing so, it is convenient to introduce an alternative representation of feasible allocations through allocation functions.$^4$

**Definition 2.3.** Given a feasible allocation $(H_A, H_B)$, the associated allocation function is $t : [0, 1] \to [0, 1]$, defined by

$$t(r) \equiv 1 - H_A \left( \inf \{ \theta : H_B(\theta) = r \} \right). \quad (2.2)$$

In the definition above, the variable $t(r)$ is the fraction of agents in organization $A$ of type higher than rank $r$’s type in organization $B$. For example, if the distribution of talents is perfectly segregated with the higher types exclusively in organization $A$, then $t(r) = 1$ for all $r$; and if there is perfect mixing so that the distribution of types is identical across the two organizations, then $t(r) = 1 - r$. Using the definition of allocation function above, we associate to each feasible allocation an (essentially) unique non-increasing function on the unit intervals. See Figure 1 for a graphical illustration of the allocation function. The infemum operator in the definition (2.2) is applied to handle the case where $H_B$ is flat over some interval (i.e. when there is local segregation with all types in the interval going to organization $A$).

Conversely, each non-increasing function $t : [0, 1] \to [0, 1]$ identifies an (essentially) unique feasible allocation $(H_A, H_B)$, where $H_B$ is given by

$$H_B(\theta) = \begin{cases} 
0 & \text{if } 2\theta \leq 1 - t(0), \\
1 & \text{if } 2\theta \geq 2 - t(1), \\
\sup \{ r : 2\theta \geq r + 1 - t(r) \} & \text{otherwise};
\end{cases}$$

$^3$ See our earlier paper for a more detailed discussion of priority equilibrium.

$^4$ The definition below does not rely on the assumption that $\theta$ is distributed uniformly on $[0, 1]$. We can represent a feasible allocation by an allocation function under any continuous type distribution. However, such representation is not directly useful because the quality difference cannot be written as an integral of the allocation function.
and where $H_A(\theta) = 2\theta - H_B(\theta)$. Thus, there is a one-to-one mapping from feasible allocations to non-increasing function on the unit interval. The convenience of working with allocation functions is made explicit by the following lemma, where we show that, for any feasible allocation, the quality difference between the two organizations only depends on the integral of the associated allocation function.\(^5\)

**Lemma 2.4.** Let $(H_A, H_B)$ be a feasible allocation and $t$ the associated allocation function. Then

$$m_A - m_B = -\frac{1}{2} + \int_0^1 t(r) \, dr.$$  

**Proof.** Using the definition of $t(r)$ and a change of variable $\theta = \inf\{\theta' : H_B(\theta') = r\}$, we can write

$$-\frac{1}{2} + \int_0^1 t(r) \, dr = \frac{1}{2} - \int_{\underline{\theta}_B}^{\overline{\theta}_B} H_A(\theta) \, dH_B(\theta),$$  

where $\underline{\theta}_B = \sup\{\theta : H_B(\theta) = 0\}$ and $\overline{\theta}_B = \inf\{\theta : H_B(\theta) = 1\}$. From the feasibility condition that $H_A(\theta) = 2\theta - H_B(\theta)$, the right-hand-side of the above equation is equal to

$$\frac{1}{2} - 2m_B + \int_{\underline{\theta}_B}^{\overline{\theta}_B} H_B(\theta) \, dH_B(\theta).$$

\(^5\) Without the assumption of uniform type distribution, we can still use equation (2.2) to relate the quality difference to the exogenous distribution function of types and the endogenous allocation function. However, the result will not be a weighted average of $t(r)$.
The claim then follows immediately from the fact that $m_A + m_B = 1$. \textit{Q.E.D.}

Since for any allocation, the quality difference between the two organizations is the integral of the allocation function minus $1/2$, we will refer to the integral

$$T = \int_0^1 t(r) \, dr$$

as the difference in quality. The constant $(T - 1/2)/\alpha$ represents the quality premium of $A$ over $B$, in that any agent would be just indifferent between the two if the agent receives from $B$ a resource greater than what he receives from $A$ by that premium. We denote the premium as a function of quality difference $T$ by

$$P(T) = \frac{T - 1/2}{\alpha}.$$ 

For any difference in quality $T \in [0,1]$, let $\underline{t}^T$ and $\overline{t}^T$ be the allocation functions defined as

$$\underline{t}^T(r) = \begin{cases} 
  1 & \text{if } S_A(0) + P(T) > S_B(r), \\
  1 - \sup \{ \tilde{r} \in [0,1] : S_A(\tilde{r}) + P(T) \leq S_B(r) \} & \text{otherwise};
\end{cases}$$

and

$$\overline{t}^T(r) = \begin{cases} 
  0 & \text{if } S_A(1) + P(T) < S_B(r), \\
  1 - \inf \{ \tilde{r} \in [0,1] : S_A(\tilde{r}) + P(T) \geq S_B(r) \} & \text{otherwise}.
\end{cases}$$

In words, the agent who has rank $r$ in $B$ must have rank at most $1 - \underline{t}^T(r)$ in $A$ or he would prefer to switch; he must also have rank at least $1 - \overline{t}^T(r)$ in $A$ or otherwise some agent from $A$ would want to switch. See Figure 2.
The following proposition identifies necessary and sufficient conditions for an allocation function to constitute a sorting equilibrium.

**Proposition 2.5.** A feasible allocation \((H_A, H_B)\) is a sorting equilibrium if and only if the associated allocation function \(t\) satisfy \(t_T(r) \leq t^T(r) \leq \bar{t}^T(r)\) for all \(r \in [0, 1]\), for \(T = \int_0^1 t(r) \, dr\).

**Proof.** Follows immediately from the definition of sorting equilibrium. \(Q.E.D.\)

Define the following correspondence

\[
D(T) = \left[ \int_0^1 t_T^T(r) \, dr, \int_0^1 \bar{t}^T(r) \, dr \right].
\]  

(2.3)

The above proposition implies that any sorting equilibrium is a fixed point \(T \in [0, 1]\) of \(D\). Existence of a sorting equilibrium then follows from an application of Tarski’s fixed point theorem.

Multiple sorting equilibria exist in general. To study the game in which the two organizations compete by choosing resource distribution schedules we must introduce an equilibrium selection in the sorting stage. We assume that organization \(A\) is dominant in that the sorting equilibrium with the largest difference in quality \(T\) is played in the sorting stage. This “\(A\)-dominant equilibrium” is unique. The equilibrium quality difference, \(T = T_A(S_A, S_B)\), corresponds to the largest fixed point of the mapping

\[
D_A(T) = \int_0^1 \bar{t}^T(r) \, dr,
\]  

(2.4)

and the equilibrium allocation function is given by \(\bar{t}_T\). We note that fixed points of \(D\) which are non-extremal may be unstable in the sense that small perturbations in the quality difference \(T\) can cause agents to switch organizations in such a way that moves \(T\) further away from the initial fixed point. On the other hand, the \(A\)-dominant equilibrium is always stable (Damiano, Li and Suen, 2005).

Now we can define a “resource distribution game” in which the two organizations simultaneously choose their resource distribution schedules to maximize their own quality. For any \((S_A, S_B)\), the payoff to organization \(i\) is defined as the average type of \(i\)’s members
in the $A$-dominant sorting equilibrium. Since the sum of the payoffs to the two organization is constant, the resource distribution game is strictly competitive, with $A$ trying to maximize the difference in quality, $T_A(S_A, S_B)$, and $B$ trying to minimize it. Therefore, a strategy profile $(S_A^*, S_B^*)$ is a Nash equilibrium of the resource distribution game if and only if

$$S_A^* \in \arg \max_{S_A \in S_A} \min_{S_B \in S_B} T_A(S_A, S_B), \quad S_B^* \in \arg \min_{S_B \in S_B} \max_{S_A \in S_A} T_A(S_A, S_B),$$

and

$$\max_{S_A \in S_A} \min_{S_B \in S_B} T_A(S_A, S_B) = \min_{S_B \in S_B} \max_{S_A \in S_A} T_A(S_A, S_B)$$

where the strategy space $S_i$ $(i = A, B)$ is the set of all non-negative, non-decreasing and almost everywhere continuously differentiable functions which respect the resource constraint $\int_0^1 S_i(r) \, dr \leq Y_i$.

3. The Minmax Value

In this section we characterize the minmax value $\min_{S_B} \max_{S_A} T_A(S_A, S_B)$. This corresponds to the maximum quality difference that organization $A$ can hope to achieve in any Nash equilibrium of the resource distribution game. We also characterize the unique resource distribution schedule $S_B^*$ that achieves the minmax value.

Before we proceed with the analysis it is useful to sketch a road map. For any resource distribution schedule $S_B$ and any difference in quality $T$, we characterize the lowest resource expenditure $C(T; S_B)$ needed for $A$ to attain a sorting equilibrium with quality difference $T$. Note that we are not requiring $T$ to be the $A$-dominant equilibrium quality difference at this point. Next, we characterize the maximum value of this minimum resource expenditure $C(T; S_B)$ that $B$ can impose on $A$ by choosing resource distribution schedule $S_B$ subject to the resource budget constraint $Y_B$. This gives us the maximum resource budget $E(T) = \max_{S_B} C(T; S_B)$. The largest $T^*$ such that $E(T^*)$ is equal to $Y_A$ is then a lower bound for

\[^6\] Since the resource distribution game is not finite, we cannot assume that maximizers and minimizers exist. These are shown to exist by construction.
the minmax value. We show that \( C(T; S_B^*) \) is larger than \( Y_A \) for all \( T > T^* \), implying that 
\( T^* \) is also an upper bound on the minmax value and therefore the minmax value. Finally, our argument also establishes a unique resource distribution schedule \( S_B^* \) that achieves the minmax value.

For \( Y_A \geq Y_B \), the A-dominant selection implies that the minmax value is at least 1/2.\(^7\) This is because, for any resource distribution schedule \( S_B \), when \( S_A = S_B \), there is a sorting equilibrium where the distributions of types in the two organizations are the same. Thus we restrict our analysis below to \( T \geq 1/2 \).

### 3.1. The expenditure minimization problem

In this subsection, we describe the potential strategies that organization A can adopt to attract talent from the weaker organization. Note that such strategies need not be observed in equilibrium, because organization B will adopt counter-measures that render A’s potential strategies ineffective. Nevertheless, understanding these potential strategies of A is essential to solving the minmax problem for B. For given \( S_B \) and some \( T \geq 1/2 \), we want to find the cheapest \( S_A \) such that \( T \) is a sorting equilibrium for \((S_A, S_B)\). If \( S_A \) is such resource distribution schedule we denote with \( C(T; S_B) \) the integral of \( S_A \). Instead of characterizing \( C(T; S_B) \) through resource distribution schedules \( S_A \), we will work with allocation functions \( t \).

First, note that by definition of \( \xi^T \), we have \( \xi^T(r) = 1 \) for all \( r \) such that \( S_B(r) < P(T) \). Thus, if \( S_B(\hat{r}) < P(T) \) for some \( \hat{r} > T \), then there is no equilibrium with quality difference \( T \) regardless of the resource distribution schedule \( S_A \). Moreover, even if A gives no resources to all of its ranks (i.e., \( S_A(r) = 0 \) for all \( r \)), there is a sorting equilibrium with quality difference strictly larger than \( T \). In this case, we write \( C(T; S_B) = 0 \).

Next, suppose \( S_B(T) \geq P(T) \). Then, for any allocation function \( t \), with \( \int_0^1 t(r) \, dr = T \) and \( t(r) = 1 \) for any \( r \) such that \( S_B(r) < P(T) \), let \( S_A^t \) be the pointwise smallest resource distribution schedule that satisfies

\[
S_A^t(1 - t(r)) \geq \max \{ S_B(r) - P(T), 0 \} \quad \text{for all } r \in [0, 1].
\]

\(^7\) If \( Y_A < Y_B \), it is more natural to focus on the B-dominant equilibrium, which corresponds to the smallest fixed point of the mapping \( D \).
See Figure 3. By construction, given the schedules $(S^t_A, S_B)$, $\bar{t}^T$ is pointwise larger than $t$ while $t^T$ is pointwise smaller than $t$. It follows that $T$ is a fixed point of the mapping (2.3) and hence there exists a sorting equilibrium with quality difference $T$ for $(S^t_A, S_B)$.

The schedule $S^t_A$ is the resource distribution schedule with the lowest expenditure for $A$ for which $t$ is a sorting equilibrium given $S_B$. It follows that

$$C(T; S_B) = \min_t \int_0^1 S^t_A(r) \, dr$$

s.t. $\int_0^1 t(r) \, dr = T$;

$$t(r) = 1 \text{ if } S_B(r) - P(T) < 0.$$ (3.1)

By definition, we have

$$\int_0^1 S^t_A(r) \, dr = \int_0^1 \max \{ S_B(t^{-1}(1-r)) - P(T), 0 \} \, dr,$$

where we define

$$t^{-1}(1-r) = \sup\{ \tilde{r} \in [0,1] : 1 - t(\tilde{r}) \leq r \}.$$

After a change of variable $\tilde{r} = t^{-1}(1-r)$ and integration by parts, we have

$$\int_0^1 S^t_A(r) \, dr = -\int_{t^{-1}(0)}^{t^{-1}(1)} \Delta(\tilde{r})t'(\tilde{r}) \, d\tilde{r} = \int_{t^{-1}(0)}^{t^{-1}(1)} t(\tilde{r})\Delta'(\tilde{r}) \, d\tilde{r} - \Delta(t^{-1}(1)),$$

where for notational convenience we have defined

$$\Delta(\tilde{r}) = \max \{ S_B(\tilde{r}) - P(T), 0 \}.$$
as the effective resource distribution schedule of the weaker organization $B$. We can then rewrite the minimization problem (3.1) as

$$\min_t \int_{t^{-1}(1)}^{t^{-1}(0)} t(r) \Delta'(r) \, dr - \Delta(t^{-1}(1)),$$

subject to

$$\int_0^1 t(r) \, dr = T,$$

where we have dropped the second constraint of (3.1) since it will be satisfied by any solution to (3.2). Note that both the objective function and the constraint are linear in the control variable $t$. This feature is used below to characterize the solution, and it is why we have chosen to deal with the allocation function instead of with type distribution functions directly.

Problem (3.2) is the continuous analog of a linear programming problem. The next lemma establishes that there exists a solution to (3.2) which assumes at most one value strictly between 0 and 1. This result is then used to provide an explicit characterization of the solution and a value for $C(T; S_B)$.

**Lemma 3.1.** For any allocation function $t$ with $\int_0^1 t(r) \, dr = T$, there exists an allocation function $\tilde{t}$ with $\int_0^1 \tilde{t}(r) \, dr = T$ which assumes at most one value strictly between 0 and 1 and satisfies

$$\int_{\tilde{t}^{-1}(1)}^{\tilde{t}^{-1}(0)} \tilde{t}(r) \Delta'(r) \, dr - \Delta(\tilde{t}^{-1}(1)) \leq \int_{t^{-1}(1)}^{t^{-1}(0)} t(r) \Delta'(r) \, dr - \Delta(t^{-1}(1)).$$

**Proof.** See the Appendix. **Q.E.D.**

The above results imply that we can restrict the search for a solution to (3.2) to allocation functions that assume at most one value strictly between 0 and 1. First, an allocation function $t$ that has just one positive value is entirely characterized by its only discontinuity point, say $\hat{r}$. To see this, note that since all solutions to (3.2) satisfy the constraint $\int_0^1 t(r) \, dr = T$, if $t$ is zero for $r > \hat{r}$ and constant for $r < \hat{r}$, then we have $t(r) = T/\hat{r}$ for all $r \leq \hat{r}$ to satisfy the constraint. Also note that $\hat{r} \geq T$ must hold in this case. Second, an allocation function $t$ that has one value strictly between 0 and 1 is entirely characterized by its two discontinuity points. Letting $r^1 = \sup\{r : t(r) = 1\}$...
and \( r^0 = \sup\{r : t(r) > 0\} \), and using the constraint \( \int_0^1 t(r) \, dr = T \), we have \( t(r) = (T - r^1)/(r^0 - r^1) \) for \( r \in (r^1, r^0) \). Note that \( r^1 \leq T \) and \( r^0 \geq T \) in this case.

Thus, a solution to problem (3.2) exists, and the value \( C(T; S_B) \) is given by

\[
\min \left\{ \min_{r \geq T} \frac{T}{r} \Delta(r), \min_{T^1 \geq r^0 ; 1 \geq r_0 \geq T} \Delta(r^1) + \frac{T - r^1}{r^0 - r^1} (\Delta(r^0) - \Delta(r^1)) \right\}. \tag{3.3}
\]

Using the above characterization for \( C(T; S_B) \) it is possible to obtain a characterization of a solution to problem (3.2) as a function of \( \Delta \). To do so, given a function \( \Delta \), we let \( \hat{\Delta} \) denote the largest convex function which is pointwise smaller than \( \Delta \) and such that \( \hat{\Delta}(0) = 0 \). Formally, \( \hat{\Delta} \) is obtained as the lower contour of the convex hull of the function \( \Delta \) and the origin. That is,

\[
\hat{\Delta}(r) = \min\{y : (r, y) \in co(\{(\tilde{r}, \tilde{y}) : 0 \leq \tilde{r} \leq 1; \tilde{y} \geq \Delta(\tilde{x})\} \cup (0, 0))\}.
\]

The next lemma provides a simple characterization of the discontinuity points of a solution to (3.2) which depends only on the functions \( \Delta \) and \( \hat{\Delta} \). In particular, it states that if \( \Delta(T) = \hat{\Delta}(T) \), then there is a solution to (3.2) with only one discontinuity point at exactly \( T \). The optimal allocation function \( t \) is step function equal to 1 for \( r \leq T \) and equal to 0 for \( r > T \). When \( \Delta(T) > \hat{\Delta}(T) \) instead, there is an optimal allocation with two discontinuity points \( r^1 < T \) and \( r^0 > T \). The two discontinuity points are determined by the largest \( r < T \) and the smallest \( r > T \) at which the function \( \Delta \) coincides with its convex hull. The optimal allocation function \( t \) equals 1 up to \( r^1 \) and becomes 0 at \( r^0 \).

**Lemma 3.2.** Let \( Q = \{r : \Delta(r) = \hat{\Delta}(r)\} \cup \{0, 1\} \). (i) If \( T \) belongs to the closure \( \overline{Q} \) of \( Q \), then the function

\[
t(r) = \begin{cases} 
1 & \text{if } r \leq T; \\
0 & \text{otherwise.}
\end{cases}
\]

solves (3.2). (ii) Otherwise, for \( r^1 = \sup\{r \in \overline{Q} : r < T\} \) and \( r^0 = \inf\{r \in \overline{Q} : r > T\} \), a solution to (3.2) is given by the function

\[
t(r) = \begin{cases} 
1 & \text{if } r < r^1; \\
(T - r^1)/(r^0 - r^1) & \text{if } r^1 \leq r \leq r^0; \\
0 & \text{if } r > r^0.
\end{cases}
\]

In both cases, the value of the objective function is \( C(T; S_B) = \Delta(T) \).
PROOF. First rewrite equation (3.3) as
\[
C(T; S_B) = \min \left\{ \min_{r \geq T} \frac{r - T}{r} 0 + \frac{T}{r} \Delta(r), \min_{T \geq r_1 \geq 0} \frac{r_0 - T}{r_0 - r_1} \Delta(r_1) + \frac{T - r_1}{r_0 - r_1} \Delta(r_0) \right\}.
\]

At the claimed solution, if \( T \in \overline{Q} \), then the value of the objective function is \( \Delta(T) = \hat{\Delta}(T) \). If \( T \notin \overline{Q} \), then the value of the objective function is given by
\[
\frac{r_0 - T}{r_0 - r_1} \Delta(r_1) + \frac{T - r_1}{r_0 - r_1} \Delta(r_0) = \hat{\Delta}(T),
\]
where the second equality holds because \( \hat{\Delta} \) is linear between \( r_1 \) and \( r_0 \). Moreover, for all \( r_1 \leq T \) and \( r_0 \geq T \), we have
\[
\hat{\Delta}(T) \leq \frac{r_0 - T}{r_0 - r_1} \hat{\Delta}(r_1) + \frac{T - r_1}{r_0 - r_1} \hat{\Delta}(r_0) \\
\leq \frac{r_0 - T}{r_0 - r_1} \Delta(r_1) + \frac{T - r_1}{r_0 - r_1} \Delta(r_0),
\]
where the first inequality follows from the fact that \( \hat{\Delta} \) is convex and the second from \( \Delta(r) \geq \hat{\Delta}(r) \) for all \( r \). Finally, for all \( r \geq T \),
\[
\hat{\Delta}(T) \leq \frac{r - T}{r} \hat{\Delta}(0) + \frac{T}{r} \hat{\Delta}(r) \leq \frac{r - T}{r} 0 + \frac{T}{r} \Delta(r).
\]

Thus \( t \) is a solution to (3.2). Q.E.D.
Figure 4 illustrates the second case of the above lemma. The total quality difference to be achieved for organization $A$ is $T$. The optimal discontinuity points $r^0$ and $r^1$ are identified in the diagram. For any other pair of discontinuity points $\hat{r}^0$ and $\hat{r}^1$, the resulting resource expenditure for $A$ is greater. The two cases in Lemma 3.2 depend on whether $T$ can be achieved by targeting a single rank $\hat{r}$ of $B$ and giving to sufficiently many ranks in $A$ the minimum resource to be competitive with $\hat{r}$, or by targeting two ranks $r^1$ and $r^0$ and giving all ranks in $A$ enough resources to compete with $r^1$ and giving sufficiently many ranks in $A$ additional resources to compete with $r^0$. Minimizing the expenditure for $A$ is then equivalent to choosing the cheapest ranks in $B$ to raid.

3.2. The budget function

For each $T \geq 1/2$, we next try to characterize the resource distribution schedule $S_B$ that makes the budget of generating an allocation with difference in quality $T$ as large as possible for $A$. More precisely, for each $T$ we study the maximization problem

$$E(T) \equiv \max_{S_B \in S_B} C(T; S_B)$$

s.t. $\int_0^1 S_B(r) \, dr \leq Y_B$.  \hspace{1cm} (3.4)

Our characterization of the strategy for expenditure minimization for $A$ in Lemma 3.2 suggests that organization $B$ would be wasting its resources if it chooses a schedule $S_B$ such that $\Delta(r) > \hat{\Delta}(r)$ for some $r$. Thus a solution to (3.4) must satisfy the condition that $\Delta(r) = \hat{\Delta}(r)$. Furthermore, if organization $A$ decides to raid some rank, say $\hat{r}$, by choosing $t(r) = 1$ for $r < \hat{r}$, there is no point for $B$ to give any resources to ranks below $\hat{r}$. On the other hand, $B$ must pay at least $P(T)$ to ranks above $\hat{r}$ if it is to compete with organization $A$. This means that for $T > 1/2$, the solution to (3.4) will involve a point of discontinuity. Our next result establishes that there is a solution $S_B$ to (3.4) with the property that it is 0 up to some critical rank $r(T)$, equal to $P(T)$ at $r(T)$, and

---

\textsuperscript{8} In the first case, the corresponding resource distribution schedule $S_A^1$ is flat and is such that the lowest type in $A$ is just indifferent between staying in $A$ at rank 0 and switching to $B$ at rank $\hat{r}$. In the second case, $S_A^2$ is a step function with two levels, such that the lowest type in $A$ is just indifferent between staying and switching to $B$ for rank $r^1$, and the lowest type receiving the higher level of resources in $A$ is just indifferent between staying and switching for rank $r^0$. 

---
Lemma 3.3. For any value of any solution to (3.4), $E$ distribution schedule $S$ on $\Delta S$. Let $\Delta \beta$ expression for the “budget function” $E$ then be used to solve explicitly for the critical threshold $r(T)$, and to obtain an analytical expression for the “budget function” $E(T)$.

Lemna 3.3. For any $S_B \in S_B$, there is $\tilde{S}_B \in S_B$ such that, for some $\tilde{r} \in [0,1]$,

$$
\tilde{S}_B(r) = \begin{cases} 
0 & \text{if } r < \tilde{r}, \\
Y B P(T) + \beta(r - \tilde{r}) & \text{if } r \geq \tilde{r}; 
\end{cases}
$$

(3.5)

where $\beta$ is determined by $\int_0^1 \tilde{S}_B(r) \, dr = Y_B$, with the property that $C(T; \tilde{S}_B) \geq C(T; S_B)$.

**Proof.** Let $\Delta S_B(r)$ denote $\max\{S_B(r) - P(T), 0\}$. First, since $C(T; S_B)$ only depends on $\Delta S_B$, it cannot be decreased if we replace $S_B$ with some $\tilde{S}_B$ such that $\tilde{S}_B(r) = 0$ whenever $\tilde{S}_B(r) < P(T)$. Second, by Lemma 3.2, $C(T; S_B) = \Delta S_B(T)$ for any resource distribution schedule $S_B$. This implies that $C(T; S_B) = C(T; \tilde{S}_B)$ if $\tilde{S}_B$ is such that $\Delta \tilde{S}_B = \Delta S_B$. Thus for any $S_B$, there is a resource distribution schedule $\hat{S}_B$ which is convex whenever positive and $\Delta \hat{S}_B(0) = 0$ such that $C(T; \hat{S}_B) \geq C(T; S_B)$. Finally, for any $S_B$ that is convex whenever positive and $\Delta S_B(0) = 0$, there is an $\tilde{S}_B$ which is linear when positive such that $C(T; \tilde{S}_B) \geq C(T; S_B)$. The lemma then immediately follows from the resource constraint because binding the constraint increases the budget requirement for the dominant organization $A$.

Q.E.D.

By Lemma 3.3, we can restrict to resource distribution schedules of the form (3.5) when characterizing a solution to (3.4). In other words, solving (3.4) boils down to finding the point of discontinuity $r(T)$ of the $S_B$ schedule. When $S_B$ has a discontinuity at $r$, the resource constraint for $B$ requires that $\beta = 2(Y_B - P(T)(1 - r))/(1 - r)^2$. Using the form of $S_B$ described in equation (3.5), we have $C(T; S_B) = \Delta S_B(T) = \beta(T - r)$. Thus, the value of any solution to (3.4), $E(T)$, is given by

$$
E(T) = \max_{r \in [0,1]} \frac{2(T - r)}{(1 - r)^2} (Y_B - P(T)(1 - r)).
$$

(3.6)

The maximization problem (3.6) can be solved analytically. In particular, it is straightforward to show that the optimal point of discontinuity $r(T)$ is given by

$$
r(T) = \begin{cases} 
T & \text{if } Y_B \leq P(T)(1 - T); \\
1 - \frac{2Y_B(1 - T)}{Y_B + P(T)(1 - T)} & \text{otherwise.}
\end{cases}
$$

(3.7)

- 17 -
We note that $r(T)$ is increasing in $T$, with $r(1/2) = 0$ and $\lim_{T \to 1} r(T) = 1$. In other words, the optimal way to deter the dominant organization from getting a higher average quality is for the weaker organization to concentrate more of its resources to reward its higher-rank members.

Substituting $r(T)$ from equation (3.7) into the cost function in (3.6), we obtain an explicit form for the budget function:

$$E(T) = \begin{cases} 
0 & \text{if } Y_B \leq P(T)(1 - T); \\
\frac{(Y_B - P(T)(1 - T))^2}{2(1 - T)Y_B} & \text{otherwise.}
\end{cases} \quad (3.8)$$

The following lemma describes the properties of this budget function.

**Lemma 3.4.** The budget function $E(T)$ satisfies $E(1/2) = Y_B$, and $\lim_{T \to 1} E(T) = \infty$. Moreover, (i) If $\alpha Y_B > 1/2$, then $E'(T) > 0$ for all $T \geq 1/2$; (ii) if $\alpha Y_B \in [1/16, 1/2]$, then there exists a $\hat{T}$ such that $E'(T) < 0$ for $T \in (1/2, \hat{T})$ and $E'(T) > 0$ for $T \in (\hat{T}, 1)$; (iii) if $\alpha Y_B < 1/16$, then there exist $T_-$ and $T_+$ such that $E'(T) < 0$ for $T \in (1/2, T_-)$; $E'(T) > 0$ for $T \in (T_+, 1)$ and $E(T) = 0$ for $T \in [T_-, T_+]$.

**Proof.** The first two properties in the statement of the lemma follows directly from substituting $T = 1/2$ and $T = 1$ into the budget function (3.8). Next, when $E(T) > 0$, its derivative has is positive if and only if

$$\alpha Y_B + (1 - T)(3T - 5/2) > 0.$$ 

The above holds for all $T \geq 1/2$ if $\alpha Y_B > 1/2$, thus establishing (i). When $\alpha Y_B \leq 1/2$, there exists a unique $\hat{T} \in [1/2, 1]$ such that the above inequality holds for $T > \hat{T}$ while the opposite inequality holds for $T < \hat{T}$. From the characterization of the budget function (3.8) we have that $E(T) = 0$ when $Y_B \leq P(T)(1 - T)$. The quadratic equation $Y_B = P(T)(1 - T)$ has two real roots $T_-$ and $T_+$ in $[1/2, 1]$ when $\alpha Y \leq 1/16$, and no real root otherwise. Claims (ii) and (iii) follow. 

See Figure 5 for the three difference cases of $E(T)$. An increase in the target quality difference $T$ has two opposite effects on the budget $E(T)$ required for $A$. On one hand, to achieve a greater $T$ organization $A$ must be competitive with more ranks in $B$ and this
requires a larger budget. On the other hand, a greater $T$ also increases the quality premium that $A$ enjoys over $B$ and this reduces the budget requirement. The first effect dominates when the peer effect is relatively small, which happens when either $\alpha$ or $Y_B$ is large. This explains why $E(T)$ is monotonically increasing in $T$ when $\alpha Y$ is large. In contrast, the peer effect is strong and $E(T)$ may decrease when $\alpha Y_B$ is small. Indeed, the budget requirement for some intermediate values of $T$ can be zero. Note that for sufficiently large $T$, the budget function must be increasing. This is because by concentrating its resources on a few top ranks organization $B$ can make it increasingly costly for $A$ to achieve large quality differences.

3.3. The minmax value and the minmax strategy

From the budget function $E(T)$ we can derive a lower bound on the minmax value. In particular, define

$$T^* = \max\{T \in [1/2, 1] : E(T) = Y_A\}. \quad (3.9)$$

Note that for $Y_A \geq Y_B$, the existence of $T^*$ follows from the characterization of the budget function in Lemma 3.4. Moreover, $T^* = 1/2$ if and only if $Y_A = Y_B \geq 1/2$. For all other values of $Y_A$ and $Y_B$ such that $Y_A \geq Y_B$, we have $T^* > 1/2$.

It is easy to see that $T^*$ provides a lower bound of the minmax value:

$$\min_{S_B \in S_B} \max_{S_A \in S_A} T_A(S_A, S_B) \geq T^*.$$
This is because \( C(T^*; S_B) \leq E(T^*) = Y_A \) for any \( S_B \), and hence there is a resource distribution schedule \( S_A \) that satisfies \( A \)'s resource constraint and the property that \( T_A(S_A, S_B) \geq T^* \).

Next, define
\[
r^* = r(T^*),
\]
and denote as \( S_B^* \) the resource distribution schedule in (3.5) with \( r = r^* \), given by
\[
S_B^*(r) = \begin{cases} 
0 & \text{if } r < r^*; \\
P(T^*) + \frac{2(Y_B - P(T^*(1-r^*)))}{(1-r^*)^2} (r - r^*) & \text{if } r \geq r^*. 
\end{cases}
\]

The next proposition establishes that the minmax value coincides with the lower bound \( T^* \) by verifying that \( C(T; S_B^*) > Y_A \) for all \( T > T^* \), so that \( T^* \) is also an upper bound of the minmax problem.

**Proposition 3.5.** The resource distribution schedule \( S_B^* \) given by (3.10) is the unique solution to the minmax problem \( \min_{S_B \in S_B} \max_{S_A \in S_A} T_A(S_A, S_B) \).

**Proof.** See the Appendix. \( Q.E.D. \)

When organization \( B \) chooses resource distribution schedule \( S_B^* \), in order to achieve the quality difference \( T^* \) organization \( A \) must expend all its available resources. However, this may fail to guarantee that a larger quality difference is infeasible for \( A \), because a larger \( T \) increases the quality premium and frees some resources for \( A \). The above proposition establishes that given \( S_B^* \), this peer effect is small relative to the additional resource requirement for obtaining a greater quality difference than \( T^* \).

4. The Nash Equilibrium

The analysis of the previous section has identified \( T^* \) as the minmax value of the resource distribution game and the resource distribution schedule \( S_B^* \) defined in equation (3.10) as

---

9 This is the first time in deriving the minmax value that we use the selection criterion of focusing on the \( A \)-dominant equilibrium. The proposition below also uses the selection criterion by establishing that there is no sorting equilibrium with quality difference greater than \( T^* \) against \( S_B^* \) defined below.
the only candidate Nash equilibrium strategy for $B$. Thus, whether a Nash equilibrium exists only depends on whether $\max_{S_A} \min_{S_B} T_A(S_A, S_B) = T^*$. Moreover, if the set of Nash equilibria is non-empty, there is a distinct Nash equilibrium for each distinct solution to the maxmin problem. A direct characterization of the set of solutions to the maxmin problem and the maxmin value is difficult. Instead we proceed by first proving that equilibrium strategies must satisfy some additional properties. By using these properties and the fact that the equilibrium strategy of $B$ is given by $S_B^*$, we identify a candidate equilibrium strategy $S_A^*$ for $A$. We then establish that a Nash equilibrium exists by directly verifying that $(S_A^*, S_B^*)$ is indeed a Nash equilibrium strategy profile. Finally, we show that $(S_A, S_B^*)$ is not a Nash equilibrium for any resource distribution schedule $S_A \neq S_A^*$, which leaves $(S_A^*, S_B^*)$ as the unique Nash equilibrium of the resource distribution game.

Using the best response properties of any pair of Nash equilibrium strategies $(S_A, S_B)$, the next lemma establishes that the range of $S_A$ and $S_B$ differ by a constant equal to the equilibrium quality premium $P(T)$.

**Lemma 4.1.** Let $(S_A, S_B)$ be a Nash equilibrium of the resource distribution game and let $T \in [1/2, 1)$ be the equilibrium quality difference. Then, the range of $S_A$ is the same as the range of the function $\max\{S_B - P(T), 0\}$.

**Proof.** Suppose that some interval $(s, \overline{s})$ is in the range of $S_A$ but not in the range of $\max\{S_B - P(T), 0\}$. Consider the resource distribution schedule $\tilde{S}_A$ defined as

$$
\tilde{S}_A(r) = \begin{cases} 
    s & \text{if } S_A(r) \in (s, \overline{s}); \\
    S_A(r) & \text{otherwise.}
\end{cases}
$$

For any $r, \tilde{r} \in [0, 1]$, and any $\tilde{T} \geq T$, we have $\tilde{S}_A(r) \geq S_B(\tilde{r}) - P(\tilde{T})$ whenever $\tilde{S}_A(r) \geq S_B(\tilde{r}) - P(\tilde{T})$. This implies that $T_A(\tilde{S}_A, S_B) = T$. Since by construction

$$
\int_0^1 \tilde{S}_A(r) \, dr < \int_0^1 S_A(r) \, dr = Y_A,
$$

there exists some other resource distribution schedule $\hat{S}_A$ such that $T_A(\hat{S}_A, S_B) > T$ and hence $S_A$ is not a best response to $S_B$. If some interval $(\underline{s}, \overline{s})$ is in the range of $\max\{S_B - P(T), 0\}$ but not in the range of $S_A$, a similar argument shows that $S_B$ is not a best response to $S_A$. Q.E.D.
The above result, together with the characterization of the unique candidate equilibrium quality difference $T^*$ and the unique candidate equilibrium resource distribution schedule $S^*_B$ of organization $B$, implies that in any Nash equilibrium, the equilibrium resource distribution schedule $S^*_A$ must be a continuous function that satisfies $S^*_A(0) = 0$ and $S^*_A(1) = S^*_B(1) - P(T^*)$.

4.1. Existence

From the characterization of the minmax strategy of organization $B$, we know that $S^*_B$ is zero up to $r^*$. Thus even the lowest type agent in organization $A$ in equilibrium will have a higher type than the agent of rank $r^*$ in organization $B$, regardless of the resource distribution schedule chosen by $A$. In terms of allocation functions, this means that the equilibrium allocation function $t^*$ will have $t^*(r) = 1$ for all $r \leq r^*$. For $r > r^*$, the equilibrium allocation function will depend on $S_A$. If $A$ wants to achieve an allocation where its rank $r'$ agents are of type higher than agents of rank $r$ in organization $B$ then it must offer $S_A(r') \geq S_B(r) - P(T^*)$. Since $S^*_B$ is linear for $r \geq r^*$, the cost minimization problem (3.1) for $A$, with $T = T^*$ and $S_B = S^*_B$, admits multiple solutions. For example, for each $r^* \leq r^1 \leq T^* \leq r^0$, the allocation

$$t(r) = \begin{cases} 
1 & \text{if } r \leq r^1; \\
(T^* - r^1)/(r^0 - r^1) & \text{if } r^1 < T^* < r^0; \\
0 & \text{if } r \geq r^0;
\end{cases}$$

solves (3.1). Moreover, for any such allocation function $t$ given by (4.1), $S_A^t(r)$ is equal to $S_B^*(r^1) - P(T^*)$ for $r < 1 - (T^* - r^1)/(r^0 - r^1)$, and equal to $S_B^*(r^0) - P(T^*)$ for $r \geq 1 - (T^* - r^1)/(r^0 - r^1)$. One can verify that

$$\int_0^{r^1} S_A^t(r) \, dr = C(T^*; S_B^*) = Y_A.$$

This implies that $T^*$ is a sorting equilibrium for $(S_A^t, S_B^*)$, and $S_A^t$ is a best response to $S_B^*$, because by the definition of $S_B^*$ we have $T_A(S_A, S_B^*) \leq T^*$ for all resource distribution schedules $S_A$ that satisfy the resource constraint.

The above strategy profile $(S_A^t, S_B^*)$, however, is not a Nash equilibrium. By construction, $S_A^t$ only assumes two values in the interval $[0, S_B^*(1) - P(T^*)]$; hence, by Lemma 4.1,
$S^*_B$ is not a best response to $S'_A$. It turns out that the space of $A$’s best responses to $S^*_B$ is not limited to resource distribution schedules of the type described above. In fact, as shown in the next lemma, any $S_A$ that exhausts the resource constraint and such that $S_A(1) \leq S^*_B(1) - P(T^*)$ is a best response to $S^*_B$.

**Lemma 4.2.** Let $S_A$ be a resource distribution schedule such that $S_A(1) \leq S^*_B(1) - P(T^*)$ and $\int_0^1 S_A(r) \, dr = Y_A$. Then $S_A$ is a best response to $S^*_B$.

**Proof.** To prove the claim it is sufficient to show that $T^*$ is a sorting equilibrium given $(S_A, S^*_B)$. By the definition of $t^{T^*}$, for a sequence of discontinuity points $(r^0, r^1, \ldots, r^k)$ such that $S^{-1}_A$ is defined on each interval $(r^j, r^{j+1})$, $j = 0, \ldots, k - 1$, we can write

$$\int_0^1 t^{T^*} \, dr = r^k - \sum_{j=0}^{k-1} \int_{r^j}^{r^{j+1}} S^{-1}_A(S^*_B(r) - P(T^*)) \, dr,$$

where $r^0$ is the smallest rank in $A$ that receives strictly positive resources and $r^k$ is the largest rank that receive an amount of resources greater than $S^*_B(1) - P(T^*)$. After a change of variable $\tilde{r} = S^{-1}_A((S^*_B(r) - P(T^*))$ and integration by parts, we can rewrite the right-hand-side as

$$r^k - \frac{1}{S^*_B} \left( S_A(1) - \int_{r^0}^1 S_A(r) \, dr \right).$$

Using the assumption that $S_A$ exhausts the resource constraint and noting that

$$(1 - r^k)S^*_B + S_A(1) = S^*_B(1) - P(T^*),$$

we can rewrite the integral of $t^{T^*}$ as

$$1 - \frac{1}{S^*_B}(S^*_B(1) - P(T^*) - Y_A).$$

Using the equation $C(T^*; S^*_B) = Y_A$, we can verify that the above expression is equal to $T^*$. This establishes that $T^*$ is a fixed point of the mapping (2.3) and hence $T^*$ is a sorting equilibrium for $(S_A, S^*_B)$. Q.E.D.

The proof of Lemma 4.2 relies crucially on the fact that $S'_B$ is constant. Recall that organization $A$ attempts to attract talents by choosing the cheapest ranks in $B$ to raid.
The weaker organization $B$ can prevent $A$ from exploiting its vulnerable ranks by making all ranks equally expensive to raid, hence the linear (beyond $r^*$) resource distribution schedule $S^*_B$. Since all ranks are equally expensive to raid, organization $A$ is indifferent between strategies that raid different ranks above $r^*$ when $B$ adopts its minmax strategy. The requirement that $S_A(1) \leq S^*_B(1) - P(T^*)$ just ensures that organization $A$ is not devoting unnecessary resources on the top ranks.

Now we are ready to establish that a Nash equilibrium exists in the resource distribution game. We have already anticipated that the proof of the next result is by construction.

In particular, with an argument similar to that in the proof of Lemma 4.2, we can show that $S^*_B$ is a best response to a resource distribution schedule $S^*_A$ which is 0 up to some rank $\hat{r} \in [0, 1]$ and has a constant slope equal to $S^*_B(1)$ above $\hat{r}$, such that $S^*_A(\hat{r}) = 0$ and $S^*_A(1) + P(T^*) = S^*_B(1)$. The proof that $(S^*_A, S^*_B)$ is a Nash equilibrium is then completed by verifying that $S^*_A$ exhausts the resource budget $Y_A$. See Figure 6 for a graphical illustration of the equilibrium schedules. Note that the origins of $S^*_A$ and $S^*_B$ are different in the diagram; the difference is precisely the quality premium $P(T^*)$.

**Proposition 4.3.** Let $\hat{r} = P(T^*)/S^*_B(1)$ and $S^*_A$ be defined by

$$S^*_A(r) = \begin{cases} 0 & \text{if } r < \hat{r}; \\ (r - \hat{r})S^*_B(1) & \text{if } r \geq \hat{r}. \end{cases}$$

The strategy profile $(S^*_A, S^*_B)$ is a Nash equilibrium of the resource distribution game.
Proof. We first verify that \( \int_0^1 S_A^*(r) \, dr = Y_A. \) By definition we have
\[
\int_0^1 S_A^*(r) \, dr = \frac{(S_B^*(1) - P(T^*))^2}{2S_B^*(1)}.
\]
From equation (3.10) for the schedule \( S_B^* \) and eliminating \( (1 - r^*) \) using equation (3.7), we have
\[
S_B^*(1) = \frac{2Y_B}{1 - r^*} - P(T^*) = \frac{Y_B}{1 - T^*}.
\]
Substituting this expression for \( S_B^*(1) \), we can verify that
\[
\int_0^1 S_A^*(r) \, dr = \frac{(Y_B - P(T^*)(1 - T^*))^2}{2(1 - T^*)Y_B} = E(T^*) = Y_A.
\]

Having established that \( S_A^* \) respects the resource constraint, we note that Lemma 4.2 and the fact that \( S_B^* \) is the minmax strategy imply \( T_A(S_A^*, S_B^*) = T^* \). Thus, to prove that \( S_B^* \) is a best response to \( S_A^* \), it is sufficient to verify that, given \( S_A^* \), for any \( S_B \in S_B \) there is a sorting equilibrium with \( T \geq T^* \). Given \( S_A^* \) and \( S_B \), from the definition of \( T^* \), we have
\[
\int_0^1 t^{T^*}(r) \, dr = 1 - \int_{r^0}^1 S_A^{-1}(S_B(r) - P(T^*)) \, dr,
\]
where \( r^0 \) is the lowest rank in \( B \) that receives more resources than \( P(T^*) \). By definition,
\[
S_A^{-1}(S_B(r) - P(T^*)) = \frac{S_B(r)}{S_B^*(1)}.
\]
Using the above expression, the resource constraint \( \int_0^1 S_B(r) \, dr \leq Y_B \) and the definition of \( S_B^*(1) \), we have
\[
\int_0^1 t^{T^*}(r) \, dr \geq 1 - \frac{Y_B}{S_B^*(1)} = T^*.
\]
Thus, \( D_A(T^*) \geq T^* \) and \( D_A \) has at least one fixed point greater than \( T^* \). Q.E.D.

As in Lemma 3.2, By using a linear resource distribution schedule for ranks that receive positive resources, organization \( A \) makes every rank equally costly for \( B \) to raid. No change to \( S_B^* \) can improve the equilibrium quality difference for \( B \). Unlike the equilibrium resource distribution schedule \( S_B^* \), there is no discontinuity for \( S_A^* \) because \( A \) does not need to pay
a quality premium to be competitive. This also means that $S^*_A$ is flatter than $S^*_B$ in the positive part.

### 4.2. Uniqueness

To establish $(S^*_A, S^*_B)$ as the unique Nash equilibrium of the resource distribution game we will argue that $S^*_B$ is not a best response to any other resource distribution schedule $S_A$ which is a best response to $S^*_B$. In proving this claim, by Lemma 4.1, we need only consider resource distribution schedules $S_A$’s that are continuous and for which $S_A(0) = 0$ and $S_A(1) = S^*_B(1) - P(T^*)$. Unfortunately, we cannot restrict further the set of candidate Nash equilibrium strategies for $A$, since by Lemma 4.2 all feasible resource distribution schedules that respect these three properties are indeed best responses to $S^*_B$. It is difficult to characterize $B$’s best responses to an arbitrary strategy $S_A$. Instead, in the proof of the next proposition we establish that $S^*_B$ is not a best response to $S_A \neq S^*_A$ by showing that an appropriately constructed “small” modification of $S^*_B$ improves $B$’s payoff. The proof considers only $S_A$’s that are strictly increasing when positive, as it is straightforward to show that this is necessary for $S^*_B$ to be a best response.

**Proposition 4.4.** The strategy profile $(S^*_A, S^*_B)$ is the only Nash equilibrium of the resource distribution game.

**Proof.** Let $S_A$ be a resource distribution schedule which is strictly increasing when positive, and which satisfies $S_A(0) = 0$, $S_A(1) = S^*_B(1) - P(T^*)$, and $\int_0^1 S_A(r) \, dr = Y_A$. We claim that if $S_A(r) + P(T^*) < rS^*_B(1)$ for some $r \in (0, 1)$, then $S^*_B$ is not a best response to $S_A$. Note that this claim is sufficient for the statement of the proposition because, by construction, $S^*_A$ is the pointwise smallest positive function for which the opposite inequality holds for all $r$, and because $S^*_A$ exhausts the resource budget, a property that all best responses to $S^*_B$ satisfy.

Given $S_A$, let $\overline{S}_A$ be the pointwise largest linear function with the property that $\overline{S}_A(r) \leq S_A(r) + P(T^*)$ for all $r$, and let $\tilde{r} = \sup\{r \in [0, 1] : \overline{S}_A(r) = S_A(r) + P(T^*)\}$. We distinguish between two cases. In the first case, we have $\overline{S}_A(\tilde{r}) > P(T^*)$. Let $r^0 =
Note that $r^0 > r^*$. For each $\epsilon > 0$ we construct the following resource distribution schedule $S_B^\epsilon$:

$$S_B^\epsilon(r) = \begin{cases} S_B^*(r) & \text{if } r \not\in (r^0 - \epsilon, r^0 + \epsilon); \\ S_B^0(r) & \text{if } r \in (r^0 - \epsilon, r^0 + \epsilon). \end{cases}$$

For all $\epsilon \leq r^0 - r^*$, $S_B^\epsilon$ respects the resource constraint. Note that for each $T$, the allocation function $\bar{t}^T(r; S_A, S_B^\epsilon)$ is given by

$$\bar{t}^T(r; S_A, S_B^\epsilon) = \begin{cases} \bar{t}^T(r; S_A, S_B) & \text{if } r \not\in (r^0 - \epsilon, r^0 + \epsilon); \\ 1 - S_A^{-1}(S_B^0(r) - P(T)) & \text{otherwise}. \end{cases}$$

It follows that

$$D_A(T; S_A, S_B^\epsilon) - D_A(T; S_A, S_B^0) = \int_{r^0 - \epsilon}^{r^0 + \epsilon} S_A^{-1}(S_B^\epsilon(r) - P(T)) \, dr - \int_{r^0 - \epsilon}^{r^0 + \epsilon} S_A^{-1}(S_B^0(r) - P(T)) \, dr.$$ 

At $T = T^*$, the first term on the right-hand-side of the above equation equals $2\epsilon \bar{r}$. To evaluate the second term, note that by definition of $\overline{S}_A$, for all $r \in [0, 1]$, we have

$$S_A^{-1}(S_B^\epsilon(r) - P(T^*)) \leq \overline{S}_A^{-1}(S_B^*(r)),$$

with strict inequality for all $r > r^0$. Hence,

$$D_A(T; S_A, S_B^\epsilon) - D_A(T; S_A, S_B^0) > 2\epsilon \bar{r} - \int_{r^0 - \epsilon}^{r^0 + \epsilon} \overline{S}_A^{-1}(S_B^\epsilon(r)) \, dr = 2\epsilon \bar{r} - \int_{r^0 - \epsilon}^{r^0 + \epsilon} \frac{S_B^\epsilon(r)}{K} \, dr = 2\epsilon \bar{r} - \int_{r^0 - \epsilon}^{r^0 + \epsilon} \frac{1}{K}(S_B^\epsilon(r^0) + \beta(r - r^0)) \, dr = 0,$$

where the second line follows from $\overline{S}_A$ being linear with some positive slope $K$, and the third from the fact that $S_B^\epsilon$ has constant slope $\beta$ for $r \geq r^*$. The last line then obtains because $\overline{S}_A(\bar{r}) = S_B^*(r^0)$.

The following properties of $D_A(\cdot; S_A, S_B^\epsilon)$ can also be established: (i) $D_A(\cdot; S_A, S_B^\epsilon)$ converges uniformly to $D_A(\cdot; S_A, S_B^0)$ as $\epsilon$ becomes small; and (ii) $D_A'(\cdot; S_A, S_B^\epsilon)$ converges uniformly to $D_A'(\cdot; S_A, S_B^0)$ as $\epsilon$ becomes small. Using property (ii), the fact that
\(D'_A(T^*; S_A, S_B^*) < 1\) and the continuity of \(D'_A(\cdot; S_A, S_B^*)\), we can establish that for sufficiently small positive \(\gamma\), we have \(D'_A(T; S_A, S_B^*) \leq 1\) for \(T \in (T^*, T^* + \gamma)\) and for all sufficiently small \(\epsilon\). Hence \(D_A(T; S_A, S_B^*) < T\) for all \(T \in [T^*, T^* + \gamma)\) and \(\epsilon\) sufficiently small. Property (i) and \(D_A(T; S_A, S_B^*) < T\) for all \(T \in [T^* + \gamma, 1]\) also imply \(D_A(T; S_A, S_B^*) < T\) for \(T\) in the same range. Hence \(T_A(S_A, S_B^*) < T^*\) for \(\epsilon\) sufficiently small and \(S_B^*\) is not a best response to \(S_A\).

In the second case, we have \(\overline{S}_A(\overline{r}) = P(T^*)\). Then, there exist \(r^0\) and \(r^1\), with \(r^0 < r^1\), such that \(S_A(r^0) = S_A^*(r^0)\), \(S_A(r^1) = S_A^*(r^1)\) and \(S_A(r) > S_A^*(r)\) for all \(r \in (r^0, r^1)\). An argument similar to the one for the first case can be used to show that a resource distribution schedule \(S_B^\epsilon\) which reduces the amount distributed to ranks just above \(S_B^* - 1(S_A(r^0) + P(T^*))\) and increases the amount of resources to ranks just below \(S_B^* - 1(S_A(r^0) + P(T^*))\) does better than \(S_B^*\) against \(S_A\). Q.E.D.

The main difficulty in the above result is that, to show that organization \(B\) can improve the quality difference \(T^*\) in its favor we must check two conditions. First, there is a modification of \(S_B^*\) for which \(T^*\) is no longer a sorting equilibrium. Second, the modified resource distribution schedule does not generate a sorting equilibrium with a quality difference strictly larger than \(T^*\). This is why it is not enough to identify the target ranks in \(A\) to for \(B\) to raid; a careful construction of the local modification of \(S_B^*\) is necessary.

5. Comparative Statics

Comparative statics analysis for the unique Nash equilibrium in the resource distribution game is straightforward. Consider, for example, a fall in the concern for the peer effect, as represented by an increase in \(\alpha\). Examining the budget function (3.8) shows that a rise in \(\alpha\) reduces the quality premium \(P(T)\) and hence shifts up \(E(T)\). Since equilibrium \(T^*\) is defined by \(E(T^*) = Y_A\), this means that equilibrium quality difference between the two organizations falls as people put less weight on the peer effect.

The degree of disparity in resources within an organization can be summarized by slope of the resource distribution schedule and by the critical rank below which members
receive no resources. We note from Figure 6 that $S^*_A$ is generally flatter than $S^*_B$, and the critical rank $\hat{r}$ for $A$ is lower than the critical rank $r^*$ for $B$. In other words, our model suggests that the organization resources are less concentrated at the top ranks in the dominant organization than in the weaker organization. Furthermore, since $r(T)$ is increasing in $T$ and decreasing in $\alpha$, a rise in $\alpha$ lowers $r^*$. For organization $A$, we have $\hat{r} = P(T^*)/S^*_B(1) = P(T^*)(1 - T^*)/Y_B$. Using the budget function (3.8) to express the condition $E(T^*) = Y_A$, we get

$$(1 - \hat{r})^2 = 2(1 - T^*)Y_A/Y_B.$$  (5.1)

Hence a fall in $T^*$ also implies a fall in $\hat{r}$. In other words, a fall in the concern for the peer effect causes both the dominant organization and the weaker organization to reduce the disparity in resources between the higher and lower ranks.

The equilibrium schedules $(S^*_A, S^*_B)$ implies the following pattern for the mixing of types across the two organizations: (i) a measure $r^*$ of the types $\theta < r^*/2$ are exclusively in the weaker organization $B$; (ii) a measure $\hat{r}$ of types $\theta \in [r^*/2, (r^* + \hat{r})/2)$ are exclusively in the dominant organization $A$; and (iii) the remaining types $\theta \geq (r^* + \hat{r})/2$ are present in both organizations, with the dominant organization $A$ getting a fraction $(1 - \hat{r})/(2 - r^* - \hat{r})$ of these top talents. When the peer effect becomes less important, both $r^*$ and $\hat{r}$ falls. Since the advantage of the dominant organization derives from the higher quality of its agents, a reduction in the importance of the peer effect increases the number of high types who are present in both organizations. Moreover, using equation (5.1), one can show that

$$\frac{1 - \hat{r}}{1 - r^*} = \sqrt{\frac{2Y_A}{Y_B(1 - T^*)}} - \frac{Y_A}{Y_B}.$$  

Hence, $(1 - \hat{r})/(1 - r^*)$ falls as $T^*$ falls. This means that when the peer effect becomes less important, the dominant organization gets a smaller share of these top talents.

We can also derive comparative statics for an increase in the resource budget of the dominant organization. Briefly, an increase in $Y_A$ raises $T^*$ because the budget function is upward sloping at $T^*$. Organization $B$ economizes on the larger quality premium $P(T^*)$ by raising the critical rank $r^*$ below which it devotes no resources. Since $\hat{r} = P(T^*)(1 -$
$T^*/Y_B$, the effect of $Y_A$ on $\hat{r}$ is positive if and only if $T^* < 3/4$. On one hand, the increase in $T^*$ and $r^*$ induces $A$ to devote more resources to the top ranks to stay competitive with $B$. On the other hand, the increase in resource budget allows $A$ to devote more resources to the lower ranks as well. Thus the overall effect on $\hat{r}$ is ambiguous. Note, however, that the slope of the schedule $S_A'$ when positive is $S_B'(1) = Y_B/(1 - T^*)$. An increase in $Y_A$ therefore always makes the schedule $S_A'$ steeper for ranks above $\hat{r}$.

An increase in $Y_B$ has an opposite effect on the equilibrium quality difference $T^*$ as an increase in $Y_A$. However, these two effects do not completely offset one another. Suppose the resource budgets of both organizations are raised by one unit. Holding $T$ fixed, the maximum cost that the weaker organization $B$ can imposed on the dominant organization $A$ is increased by more than one unit, because

$$\frac{\partial E(T)}{\partial Y_B}\bigg|_{T=T^*} = \frac{Y_B^2 - (P(T^*)(1 - T^*))^2}{2(1 - T^*)Y_B^2} = \frac{Y_A(1 + \hat{r})}{Y_B(1 - \hat{r})} > 1.$$ 

Hence, organization $A$ cannot afford to maintain the same quality difference even if its own resources are raised by an equal amount. The result is that equilibrium quality difference $T^*$ falls.\footnote{The same conclusion holds if $Y_A$ and $Y_B$ are increased by the same proportion.} The availability of greater resources to the two organizations induces these organizations to compete for talents by appealing to their concern for the pecking order effect. As a result, the relative importance of the peer effect diminishes. The effect of an equal increase in budgets is therefore similar to that of an increase in $\alpha$.

So far, we have assumed that organizations $A$ and $B$ are identical except for the fact that $Y_A \geq Y_B$ and we focus on the $A$-dominant sorting equilibrium. Other differences between the two organizations can be introduced into the model by assuming that the utility from joining organization $A$ is

$$V_A(\theta) = \alpha S_A(r_A(\theta)) + m_A + u.$$ 

One can think of the parameter $u$ as the natural advantages (such as locational attraction) of $A$ relative to $B$, assumed to be common to all types of agents. In this setting, the quality premium is $P(T) = (T + u - 1/2)/\alpha$. An increase in $u$ has the effect of shifting down the
budget function $E(T)$, thereby raising the equilibrium quality difference $T^*$. Organization $B$ responds to this by raising the critical rank $r^*$ below which its members receive no resources. Organization $A$ also raises its critical rank $\hat{r}$ in equilibrium, because its natural advantages already offer a large rent to intermediate talents at its lower ranks. The result of this is that there is more intense competition for top talents, with a greater disparity in resource distribution within each organization.

6. Discussion

The equilibrium pattern of mixing and segregation differs from what we derived in a benchmark two-organization model of Damiano, Li and Suen (2005). In the earlier paper, we have the “overlapping interval” structure, where the very talented are captives in the high quality organization and the least talented are left to the low quality organization, while the intermediate talents are present in both. The focus of the earlier paper is on comparative statics analysis with respect to factors that affect the tradeoff between the peer effect and the pecking order effect, and on competitive equilibrium implementation and welfare implications. To the extent that the tradeoff is affected by resource distribution policies of organizations, these policies are exogenously fixed in that paper, rather than chosen in a strategic game. In the present paper, we model the pecking order effect as concern for allocation of organizational resources, and derive equilibrium sorting pattern by solving the resource distribution game between the organizations. Thus, intermediate types mix across organizations when the tradeoff between the peer effect and the pecking order effect does not respond to organizational choices, while top talents attract organizational competition when the tradeoff can be directly affected by organizational strategies.

In our model of organizational competition for talents, we have assumed that there is a fixed budget of resources for each organization. We view this as a reasonable approximation of competition in the short term before production by the members generates any impact on available resources. Another interpretation is that organizations we model are not-for-profit, so that the objective of the organization is not to maximize the profit in terms of the difference between total output and the resources expended to attract productive members, but is instead to use the fixed resources to attract the best average quality.
Organizations in our model have a fixed capacity of half of the talent pool and must fill all positions. In particular, an organization cannot try to improve its average talent by rejecting low types even though the capacity is not filled. We have made this assumption in order to circumvent the issue of size effect, and focus on implications of sorting of talents. Alternatively, we can justify the assumption of fixed capacity if the peer effect enters the preferences of talents in the form of total output (measured by the sum of individual types) as opposed to the average type, and the objective of the organization is to maximize the total output. Since all agents contribute positively to the total output, in this alternative model all positions will be filled.

We have restricted organization strategies to meritocratic resource distribution schedules. This is a natural assumption given how we model the sorting of talents after organizations choose their schedules. Non-meritocratic resource distribution schedules would create incentives for talented agents to “dispose of” their talent. Another assumption we have made about organization strategies is that resource distributions do not depend on type directly. This is a reasonable assumption in the presence of the resource constraint; a resource distribution schedule that depends directly on type might exceed the resources available or leave some resources unused depending on the distribution of types that join the organization. Moreover, at the equilibrium quality difference and against the equilibrium resource distribution schedule of the rival organization, each organization cannot improve its quality by deviating to a resource distribution schedule that depends on type as well as on rank. This is because any sorting equilibrium after such a deviation can be replicated by a deviating schedule that depends on type only. Our equilibrium is thus robust to deviations allowed by a richer strategy space.

Our main results of linear resource distribution schedules rely on the assumption of uniform type distribution. This assumption implies that the impact on the quality difference of an exchange of one interval of types for another interval between the two organizations depends only on the difference in the average types of the two intervals. This property allows us to transform the minmax problem in resource distribution functions to a linear programming problem in allocation functions. We leave the question of whether the method we develop in this paper is applicable to more general type distributions to future research.
Appendix

A.1. Proof of Lemma 3.1

We first prove that ˜\(t\) assumes a countable number of values, and then show that it assumes at most one value strictly between 0 and 1.

To establish the first claim, let \(\mathcal{I}\) denote the collection of all open intervals \(I \subset [0, 1]\) such that: (i) \(t\) is continuous and strictly decreasing on \(I\); (ii) \(\Delta'\) is monotone on \(I\); and (iii) there is no open interval \(I' \supset I\) that satisfies properties (i) and (ii). Since both \(t\) and \(\Delta'\) have a countable number of discontinuities, the set \(\mathcal{I}\) is countable. Moreover, \(t\) assumes a countable number of different values on \([0, 1] \setminus \mathcal{I}\). If \(t\) assumes uncountably many values, then \(\mathcal{I}\) is non-empty. For each \(I \in \mathcal{I}\), let \(r_- = \inf r I\) and \(r_+ = \sup r I\). Let \(r^0 \in (r_-, r_+)\) solve

\[
(r_+ - r_-)t(r^0) = \int_{r_-}^{r_+} t(r) \, dr,
\]

and let \(\hat{r} \in (r_-, r_+)\) solve

\[
(\hat{r} - r_-)t(r_-) + (r_+ - \hat{r})t(r_+) = \int_{r_-}^{r_+} t(r) \, dr.
\]

We construct a new allocation function \(\tilde{t}\) such that, for each \(I \in \mathcal{I}\), if \(\Delta'\) is decreasing on \(I\), then \(\tilde{t}(r) = t(r^0)\) for all \(r \in I\). Otherwise, if \(\Delta'\) is increasing on \(I\), then \(\tilde{t}(r) = t(r_-)\) for all \(r \in (\hat{r}, r_+)\) and \(\tilde{t}(r) = t(r_+)\) for all \(r \in (r_-, \hat{r})\). On \([0, 1] \setminus \mathcal{I}\), \(\tilde{t}\) is identical to \(t\).

By construction \(\tilde{t}\) is a decreasing function and

\[
\int_0^1 \tilde{t}(r) \, dr = \int_0^1 t(r) \, dr.
\]

Moreover,

\[
\int_0^1 S^\tilde{t}_A(r) \, dr - \int_0^1 S^t_A(r) \, dr = \sum_{I \in \mathcal{I}} \int_{r_-}^{r_+} (\tilde{t}(r) - t(r)) \Delta'(r) \, dr.
\]

For each \(I \in \mathcal{I}\) such that \(\Delta'\) is decreasing,

\[
\int_{r_-}^{r_+} (\tilde{t}(r) - t(r)) \Delta'(r) \, dr = \int_{r_-}^{r^0} (t(r^0) - t(r)) \Delta'(r) \, dr + \int_{r^0}^{r_+} (t(r^0) - t(r)) \Delta'(r) \, dr \leq \Delta'(r^0) \int_{r_-}^{r^0} (\tilde{t}(r^0) - t(r)) \, dr + \Delta'(r^0) \int_{r^0}^{r_+} (\tilde{t}(r^0) - t(r)) \, dr = 0.
\]
For each $I \in \mathcal{I}$ such that $\Delta'$ is increasing,
\[
\int_{r_-}^{r_+} (\tilde{t}(r) - t(r)) \Delta'(r) \, dr = \int_{r_-}^{\tilde{r}} (t(r_-) - t(r)) \Delta'(r) \, dr + \int_{\tilde{r}}^{r_+} (t(r_+) - t(r)) \Delta'(r) \, dr \\
\leq \Delta'(\tilde{r}) \int_{r_-}^{\tilde{r}} (t(r_+) - t(r)) \, dr + \Delta'(\tilde{r}) \int_{\tilde{r}}^{r_+} (t(r_-) - t(r)) \, dr \\
= 0.
\]

Therefore the first claim follows.

We can now restrict attention to allocation functions $t$ which assume a countable number of values. Suppose there are two consecutive intervals $I^j$ and $I^{j+1}$, such that $t$ assumes value $t^j$ on $I^j$ and value $t^{j+1}$ on $I^{j+1}$, for some $1 > t^j > t^{j+1} > 0$. Consider a new allocation function $\tilde{t}_\epsilon$ defined as follows:
\[
\tilde{t}_\epsilon(r) = \begin{cases} 
  t^j + \epsilon/(r^+_j - r^-_j) & \text{if } r \in I^j; \\
  t^{j+1} - \epsilon/(r^{j+1}_+ - r^{j+1}_-) & \text{if } r \in I^{j+1}; \\
  t(r) & \text{otherwise}.
\end{cases}
\]

For $\epsilon$ small, $\tilde{t}_\epsilon$ is a decreasing function. Moreover, by construction, $\int_0^1 \tilde{t}_\epsilon(r) \, dr = \int_0^1 t(r) \, dr$ and
\[
\int_0^1 S^\tilde{t}_\epsilon_A(r) \, dr - \int_0^1 S^t_A(r) \, dr = \frac{\epsilon}{r^+_j - r^-_j} \int_{r^-_j}^{r^+_j} \Delta'(r) \, dr - \frac{\epsilon}{r^{j+1}_+ - r^{j+1}_-} \int_{r^{j+1}_-}^{r^{j+1}_+} \Delta'(r) \, dr.
\]

Since $\int_0^1 S^\tilde{t}_A(r) \, dr - \int_0^1 S^t_A(r) \, dr$ is linear in $\epsilon$, we can always choose some $\epsilon$ for which $\tilde{t}$ assumes one less value than $t$ and does at least as well as $t$ for the objective function of (3.2). $\quad \Box$

### A.2. Proof of Proposition 3.5

To establish the upper bound, note that from Lemma 3.2, we have $C(T; S^*_B) = S^*_B(T) - P(T)$. Using the formula (3.10) for the schedule $S^*_B$, we then have
\[
C(T; S^*_B) = \frac{2(T - r^*)}{(1 - r^*)^2} (Y - P(T^*)(1 - r^*)) + P(T^*) - P(T).
\]
Since $C(T; S_B^*)$ is linear in $T$ and $C(T^*; S_B^*) = Y_A$ by the definition of $T^*$, it is the case that $C(T, S_B^*) > Y_A$ for all $T > T^*$ if and only if

$$\frac{2(Y_B - P(T^*)(1 - r^*))(1 - r^*)}{(1 - r^*)^2} - \frac{1}{\alpha} > 0.$$  

Using the condition that $C(T^*, S_B^*) = Y_A$, the above inequality is equivalent to

$$\alpha Y_A - (T^* - r^*) > 0. \quad \text{(A.1)}$$

To prove that condition (A.1) is true, we proceed in two steps. We first establish that $\alpha Y_A - (T^* - r^*) > 0$ when $Y_A = Y_B$. Then we show that $\alpha Y_A - (T^* - r^*)$ is increasing in $Y_A$, and hence condition (A.1) is true for all $Y_A > Y_B$.

For the first step, let $T' = \max\{T \in [1/2, 1] : E(T) = Y_B\}$ and let $r' = r(T')$. Condition (A.1) for the case $Y_A = Y_B$ is equivalent to $\alpha Y_B - (T' - r') > 0$. For $T' > 1/2$, use the explicit formula of $E(T)$ in equation (3.8) to obtain

$$\alpha Y_B = (1 - T') \frac{1 + \sqrt{2(1 - T')}}{2}.$$  

Use this expression and the explicit formula for $r(T)$ in equation (3.7) to obtain

$$T' - r' = (1 - T') \frac{2(1 - T') + \sqrt{2(1 - T')}}{2T' + \sqrt{2(1 - T')}}.$$  

It is straightforward to verify that $\alpha Y_B > T' - r'$. For $T' = 1/2$, it must be the case that $\alpha Y_B > 1/2$ and $r' = 0$. Hence the condition $\alpha Y_B > T' - r'$ also holds.

Next, we show that $\alpha Y_A - (T^* - r^*) > 0$ whenever $\alpha Y_B - (T' - r') > 0$. To this end, use equation (3.7) for $r(T)$ to write

$$T^* - r^* = (1 - T^*) R(T^*),$$  

where $R(T) = (Y_B - P(T)(1 - T))/(Y_B + P(T)(1 - T))$. Also Use equation (3.8) for $E(T^*) = Y_A$ to get

$$\alpha Y_A - (T^* - r^*) = (1 - T^*) R(T^*) \left( \frac{2 \alpha Y_B R(T^*)}{(1 - r^*)^2} - 1 \right).$$
There are two cases to consider. (i) Suppose $R(T)$ is decreasing. In this case, $(1 - T^*)R(T^*) < (1 - T')R(T')$ since $T^* > T'$. Therefore, $\alpha Y_A -(T^* - r^*) > \alpha Y_B -(T' - r') > 0$. (ii) Suppose $R(T)$ is increasing. In this case, $R(T^*)/(1 - r^*)^2 > R(T')/(1 - r')^2$ since $T^* > T'$ and $r^* > r'$. So $\alpha Y_B -(T' - r') > 0$ implies $\alpha Y_A -(T^* - r^*) > 0$. Q.E.D.
