Anticompetitive Product Design in the New Economy

John M. Newman
ABSTRACT: Claims alleging anticompetitive product design and redesign lie at the very core of one of antitrust law’s most challenging dilemmas: the intersection between innovation and regulation, invention and intervention. For over three decades, courts and scholars have struggled to determine the proper analytical framework within which to address such cases. Meanwhile, the very industries in which challenged conduct occurs have been undergoing fundamental changes.

As demonstrated by the ongoing and recent antitrust litigation involving high-technology firms Apple, Intel, and Microsoft, distinctive features characterize most product markets in what has been called the “New Economy”—and increasingly has become simply “the economy.” Many of these features not only uniquely incentivize anticompetitive design-related conduct, but also render such conduct uniquely susceptible to antitrust scrutiny. Accordingly, this Article both supplies a proper understanding of code-based product markets and, perhaps more importantly, provides a structured, efficient, and rational method of analyzing design-related conduct in those markets.

VI. CONCLUSION
I. **INTRODUCTION**

“Innovation” has come to be broadly regarded as one of the primary factors in achieving increased consumer and societal wealth.\(^1\) As such, it has also become an increasingly prized goal of antitrust law.\(^2\) And consequently, antitrust courts have traditionally been hesitant to condemn unilateral conduct related to product design and redesign for fear that such decisions will place an undue chill on innovation in the marketplace.\(^3\)

The archetypical design-conduct challenge alleges that a firm, dominant in one product market, designed a new version of that product so as to maximize interoperability with its own complementary product(s), essentially requiring customers to buy the two together. Thus, the theory goes, the defendant either engaged in “foreclosure” (excluding from the market rivals who make interoperable complementary goods), “leveraging” (extracting overcharges from customers in the complementary-good market), or both. Such conduct is often referred to as “technological tying” because of its similarity to contractual tying.\(^4\) And as with contractual tying, a healthy debate surrounds the viability of claims that it is anticompetitive.\(^5\)

Yet, perhaps because the early cases consisted of similar fact patterns, too much emphasis has been placed on this resemblance to traditional tying, which tends to focus on the controversial “leveraging” theory of antitrust harm. The possibilities for firms to engage in anticompetitive product design and redesign are broader than technological tie-ins, particularly in markets for digital, or computer-code-based, products. Take, for instance, a dominant manufacturer of central-processing units (“CPUs”) for personal computers that also creates “compilers,” software programs that expert computer programmers use in developing new software.\(^6\) If the firm were to design or redesign its compilers such that the resulting software runs slower on personal computers that use rivals’ CPUs, its conduct would have the effect of

---

1 See Gaia Bernstein, *In the Shadow of Innovation*, 31 CARDOZO L. REV. 2257, 2258 & n.3 (2010) (“We put brilliance, creativity, and innovation up on a pedestal, often tying these qualities to progress and overall improvement in human welfare.”).

2 See, e.g., U.S. DEP’T OF JUSTICE & FED. TRADE COMM’N, 2010 HORIZONTAL MERGER GUIDELINES, at 23 (devoting an entire subsection to “Innovation and Product Variety” and stating that enforcement agencies account for effects on innovation in conducting merger reviews).

5 Compare Einer Elhauge, *Tying, Bundled Discounts, and the Death of the Single Monopoly Profit Theory*, 123 HARV. L. REV. 397, 399 (2009) (“Even without a substantial foreclosure share, tying by a firm with market power generally increases monopoly profits and harms consumer and total welfare, absent offsetting efficiencies.”), with Erik Hovenkamp & Herbert Hovenkamp, *Tying Arrangements and Antitrust Harm*, 52 ARIZ. L. REV. 925, 927 (2010) (“The great majority of ties are beneficial or at least benign, measured by either welfare standard, and this is true without even considering production efficiencies that many ties produce.”).

6 This fact pattern is broadly drawn from *In re Intel*, but it is not intended to pass judgment on the defendant’s behavior in that case.
prolonging its CPU monopoly by foreclosing those rivals from the market. And if the dominant firm did so with no plausible procompetitive justification, its behavior was anticompetitive.

Thus, this Article looks beyond conduct involving technologically tied products and more generally toward product design and redesign in the product markets that characterize what has been called the “New Economy” and increasingly has become simply “the economy.” Here, the focus is on the destruction of interoperability between a dominant firm’s products and those of its rivals—foreclosure, rather than leveraging. The product markets that dominate the new economy are technology-intensive and based on intangible computer code, unlike the physical-based product markets traditionally subject to antitrust scrutiny. And, I argue, these new markets have distinctive features that not only uniquely incentivize anticompetitive design-related conduct, but also render such conduct uniquely susceptible to antitrust scrutiny.

Part II of this Article addresses the functioning of code-based product markets, focusing on their tendency to be characterized by positive network externalities. It contends that this tendency, combined with a number of other factors, serves to refute the argument that antitrust scrutiny is inappropriate in these markets. Part II concludes with a discussion of some general principles of anticompetitive harm in new-economy product markets.

In Part III, I begin by first discussing the mechanics of designing and redesigning code-based software products, then introducing the ongoing Apple FairPlay antitrust litigation as an example of how software updates, the principal method of redesigning software programs, can be used by a dominant firm to exclude rivals from a closed network market. Part III concludes by demonstrating: (1) that software updates are a uniquely attractive method of using product redesign to foreclose rivals, and (2) that code-based product redesign is uniquely susceptible to antitrust scrutiny.

7 Another term frequently used to describe anticompetitive design-related conduct is “predatory innovation.” See, e.g., Joseph Gregory Sidak, Debunking Predatory Innovation, 83 COLUM. L. REV. 1121 (1983). As a label, however, it is (to at least some extent) conclusory, “[a]nd conclusory labels fall prey to hopeless circularity.” Richard D. Cudahy & Alan Devlin, Anticompetitive Effect, 95 MINN. L. REV. 59, 59 (2010). More specifically, the term itself begs the question by assuming that behavior can be at once both “predatory” and truly “innovative.” Yet, as argued infra, in the product markets under discussion herein, this is rarely—and indeed, likely never—the case.

9 See Orrin G. Hatch, Antitrust in the Digital Age, in COMPETITION, INNOVATION AND THE MICROSOFT MONOPOLY: ANTITRUST IN THE DIGITAL MARKETPLACE 22 (Jeffrey A. Eisenach & Thomas M. Lenard eds., 1999) (“High technology is the single largest industry in the United States, leading all other sectors in terms of sales, employment, exports, and research and development.”).

10 See Dan Hunter, Culture War, 83 TEX. L. REV. 1105, 1107 (2005) (“As the modern era advanced, the importance of industrial production waned. No longer was heavy machinery and physical plant the predominant means of production; no longer was physical inventory the most important asset to industry.”).
Part IV of this Article begins by assessing the landmark product-design decisions, underlining the various approaches used by courts in addressing design claims—and foreshadowing the ineptitude of the various analytical frameworks used to date for addressing such conduct. It also serves to re-emphasize the burgeoning potential for anticompetitive product design and redesign in code-based product markets.

Finally, Part V examines and rejects the various standards employed by courts and advanced by scholars as inappropriate for assessing design-related claims involving code-based products. In their stead, it offers a structured, rational, and efficient analytical framework for assessing design-related claims. Crucially, this method of analysis allows the avoidance of both an overly defendant-friendly default rule and the inherent uncertainty of “balancing” anticompetitive effects against innovative justifications.

II. TECHNOLOGY-INTENSIVE AND CODE-BASED PRODUCT MARKETS

“Whatever faults this world has, it at least cannot be charged with being petrified; on the contrary it transforms itself unceasingly.”

- Charles Gide

Much has been said about the “New Economy,” the paradigm shift away from an economy based on physical goods and networks to digital ones. What, exactly, is meant by this phrase tends to differ depending on who is using it. Generally speaking, it refers to a trend towards an information-based economy—and away from the heavy focus on physical manufacturing and industrialization that characterized much of the early- to mid-twentieth century. It encompasses primarily digital technological innovations that

---

12 The term “paradigm shift” originated in Thomas Kuhn’s seminal The Structure of Scientific Revolutions and described a dramatic change in the paradigms underlying a prevailing theory of scientific study. See THOMAS KUHNS, THE STRUCTURE OF SCIENTIFIC REVOLUTIONS 85 (1962). It has, however, subsequently entered the popular lexicon as a phrase more loosely describing any major change in political, social, artistic, or commercial structures, and it is in this latter sense that I employ the term.
14 See Hunter, supra note __, at 1107.
have allowed for sizable increases in productivity and an accompanying shift in the number and type of occupations available and sought after in the workplace. And it identifies a change in the way everyday consumers purchase—or decline to purchase—products, a change spurred on by the speed and ease of transmission of information allowed by these new digital technologies. Witness, for example, the rapid rise of online retailing, a means of commerce entirely unknown to firms and consumers only a few short decades ago.

Yet the degree to which this economy is really “new,” and the implications the answer to that question holds for antitrust law and policy, are unclear. Some argue the concept of a “new” economy is merely, or at least largely, the product of semantics. And it is true the phrase itself is hardly new, having appeared in literature at least as far back as the late 1800s. “But it is safe to say that the economy has changed in the last decade or so, and that these changes are of sufficient importance to deserve the title ‘New Economy.’” And the changes that have occurred are due primarily to changes in the ways in which society—individuals—access, process, store, and communicate information. Those changes have been facilitated by two primary technological developments: (1) the advent of affordable, personal, digital computing devices, and (2)

See Dennis W. Jansen, The New Economy and Beyond: Past, Present and Future 2–3 (2006). The annual growth rate of average labor productivity declined precipitously from 1974 to 1995, averaging 1.44% per year during that period. Yet from 1995 to 2000, the growth rate averaged 2.36% per year, an increase attributable largely to advances in information technology.

See Hatch, supra note __, at 22.

In 2008, e-commerce in retail-trade industries totaled $141 billion. U.S. Census Bureau, Statistical Abstract of the United States: 2011, at tbl. 1054 (2011), available at http://www.census.gov/compendia/statab/2011/tables/11s1054.pdf. At only 3.6% of total sales, id., online retailing has certainly not yet come to dominate these markets. Yet considering that, in recent memory, retail revenues from e-commerce totaled $0.00, the $141 billion figure is substantial.

Jean Gadrey, New Economy, New Myth 1 (2003). As Professor Gadrey memorably stated: We have entered a new age, we are told. Its characteristics are ill-defined, the issues at stake uncertain, but we are told it is new and that we have to go along with it. The myths put about to stir people into action are flourishing, but little serious thought is being given to the general nature of this new age or to the social risks we might have to guard against. Trenchant turns of phrase and portmanteau words seem to be sufficient. However, these new words and the old ones have many points in common.

Id.

Attorney (and ardent socialist) Laurence Gronlund used the phrase in 1898 as the title of his major work, a cry that “[s]omething must be done!” about the emergence of an unrivalled threat to workers: the Trust. Gronlund, supra note __, at 15.

Jansen, supra note __, at 2.

Cf. Posner, supra note __, at 925 (“I shall use the term ‘new economy’ to denote . . . the manufacture of computer software . . . Internet-based businesses . . . [and] communications services and equipment designed to support the first two markets.”).
the rise of inexpensive, high-speed, readily available access to the Internet, utilizing those devices.

These two developments have given rise to a wealth of new industries that differ widely from the paradigmatic firms around which antitrust doctrine grew and developed. Traditional antitrust targets were industries that manufactured or were based upon physical products: oil, steel, railroads, tobacco, etc. These industries tended to be relatively stable; entry and exit (and even substantial market-share shifts) were rare. Entry entailed relatively high sunk costs, and economies of scale offered existing market participants substantial advantages over potential entrants. Firms also incurred both fixed and variable costs throughout their production cycle, with average variable cost rising even at relatively low levels of output. On the whole, these tended not to be characterized by positive network externalities (aside from the railroads and the telecommunications industry, the archetypical network industry). And the pace of innovation was modest.

The nascent industries that have been built around digital computers and the Internet, on the other hand, use intangible—instead of physical—means as the dominant means of production. The products and services they offer increasingly consist largely (or even solely) of computer code. As a result, intellectual-property protections became an increasingly crucial incentive to firms. They frequently exhibit positive network externalities. Firms tend to face high fixed costs and very low variable costs (approaching zero). The barriers to creating entirely new products tend to be lower, and innovations—perhaps as a result of this—appear to be more frequent.

---

22 The increase in the numbers of Americans with ready Internet access has been unbelievably precipitous—take, for example, the second half of the year 2000, when “the number of American adults with Internet access grew from about 88 million to more than 104 million.” LEE RAINIE & DAN PACKEL, PEW INTERNET PROJECT, MORE ONLINE, DOING MORE 2 (2001).

25 See Bernstein, *supra* note 1, at 2262.

26 See Bernstein, *supra* note 1, at 2262.

27 See Bernstein, *supra* note 1, at 2262.

28 *Id.* (“As the dominant means of production changed from the physical to the intangible, the determination of the appropriate scope of intellectual property rights became more crucial.”)

29 See Posner, *supra* note __, at 926 (referring to positive network externalities as “economies of scale in consumption”).

30 See LAWRENCE LESSIG, THE FUTURE OF IDEAS: THE FATE OF THE COMMONS IN A CONNECTED WORLD 120 (2002) (“The barriers of cyberspace in its natural state are radically different from the barriers in real space.”).
A. The Operation of the Markets: Stable Network Markets, Innovation-Based Rivalry—or Both?

As noted above, the product markets that have emerged in the New Economy are both dynamic and different from the industries that dominated the economy in the past. Multiple explanations have emerged for this dynamism; perhaps the two foremost (and competing) theories advanced are the impact of network effects and innovation-based, or “Schumpeterian,” rivalry. Both have a part to play in determining antitrust’s role in evaluating product design and redesign in these markets.

1. Network Markets and Effects

Network markets are those markets in which one user of a good or service impacts, through her use, the value of that good or service to other users. As an initial matter, a network may be either “closed” or “open.” A “closed” network is controlled by one firm, which limits full access to the network.31 An “open” network, on the other hand, may be fully accessed by all who wish to do so. All networks, however, are characterized by “network effects,” a term that is sometimes used in place of “positive network externalities” (described further below), but that more properly includes all effects one user can have on the value of a product to other users in a network market.

Network effects can be direct or indirect. “Direct” network effects occur where an additional use or user causes a direct impact on the value of the product to other users. “Indirect” network effects, on the other hand, occur where an increase in usage incentivizes firms to produce additional complementary goods, increasing the value of the original product to all users.

a. Positive Network Externalities

Network markets are frequently characterized by positive network effects, or “externalities”—“benefits to society that accrue as the size of a network grows.”32 In a network market, the value to each individual consumer increases with the number of other individuals who use the same network.33 Take, for example, a telephone network. If very few telephones existed, I would not value a telephone very highly, or at least not nearly as highly as I do today. The more individuals who use the telephone network, the more individuals I am able to reach with my own telephone—and the more valuable my phone becomes to me. Thus, telephone networks allow for direct, positive network externalities.

Many of the industries that have arisen from the advent of digital computers and broadly available Internet access exhibit similar positive network externalities, both

31 It should be noted, however, that a closed network does not necessarily dominate or constitute a product market.
33 Another term sometimes used to describe this phenomenon is “economies of scale in consumption.” See, e.g., RICHARD A. POSNER, ANTITRUST LAW 246 (2001).
direct and indirect. Online social-networking sites like Facebook allow for direct, positive effects (much like the telephone industry). And a broad range of product markets allow for indirect, positive network externalities. Take, for example, Apple’s iPod: as more individuals purchase iPods, Apple is increasingly incentivized to invest in adding songs to its iTunes Music Store, thereby increasing the value of the iPods. The current market for Blu-Ray DVD players operates similarly, as does the market for Microsoft’s Windows OS. These positive network externalities that tend to characterize new, digital industries can, however, have less benign implications.

b. The “Side Effects” of Network Markets

If its product is not interoperable with rivals’ products, a first-mover or firm with a relatively large market share at an early stage in a network market can gain a decisive advantage over other firms in the market simply by virtue of its early lead. This is so “because consumers are attracted to the good or service that offers the largest network benefit, and that benefit then only becomes larger and more attractive to later consumers.” Thus, a network owner is faced with a choice. First, it can choose to allow interoperability with competitors’ products, thereby increasing the number of users in the network and increasing the network’s value to all users. On the other hand, it may refuse to interconnect, which “would lead to a race to become the dominant player.” Absent interoperability, consumers will desire to be a part of the largest network, which naturally offers the most value. Less risk-averse consumers will buy into the network early on, predicting that more consumers will follow (increasing the value of the early consumers’ investment). At some point, consumers will perceive that a certain product will become dominant and accordingly flock to that product—a phenomenon known as the market’s “tipping point.” And “[o]nce the market reaches its tipping point, the

34 See id. at 245–46; see also Aran Sundararajan, Network Effects, IOIT, http://oz.stern.nyu.edu/io/network.html (last visited Mar. 26, 2011) (“Today, [network effects] are widely recognized as a critical aspect of the industrial organization of IT industries, and are prevalent in a wide variety of sectors, including software, microprocessors, telecommunications, e-commerce and electronic marketplaces.”).

35 It is perhaps worth venturing to predict that, as consumers move further and further into the “cloud,” such physical-disk-based technology will eventually go the way of the dinosaur and the VCR, demonstrating the effect that innovation can sometimes play—even in network markets.

36 Shelanski & Sidak, supra note __, at 8–9.

38 See, e.g., William J. Baer & David A. Balto, New Myths and Old Realities: Recent Developments in Antitrust Enforcement, 1999 COLUM. BUS. L. REV. 207, 221 n.47 (“Particularly in markets characterized by networks, an industry may reach a ‘tipping’ point where manufacturers of complementary products adopt the dominant technical standard of those products with which interface is necessary, or consumers adopt the product that is most favored by other consumers.”).
value of the network of the dominant player will so far outstrip that of its competitors that the market collapses into a natural monopoly.”

The possibility of charging higher-than-marginal-cost prices acts as a powerful incentive for firms to avoid interoperability and instead attempt to become the dominant firm in a closed network market. Thus, in network markets, the good or service that constitutes the market is frequently produced by only one firm, and is frequently not interoperable with competing goods or services. Consumers who have bought the dominant firm’s product in order to obtain the larger value conferred by the larger network would have to incur switching costs in order to purchase or begin using a competitor’s product. And as a result, “consumers may become ‘locked in’ to a particular market,” creating a barrier to potential entrants. Consequently, the dominant firm may become entrenched. Further, that firm’s design choices will determine the market’s technological standard—and later inventions will have to follow the “path” set

39 Spulber & Yoo, supra note 37, at 1890. A relatively recent example of this phenomenon was the high-definition optical-disc format war that took place from around 2006 to 2008. The HD DVD and Blu-Ray formats struggled for dominance until the market reached a tipping point early in 2008, with several major manufacturers announcing that they were exclusively adopting the Blu-Ray format. Very shortly thereafter, Toshiba issued a press release indicating that it planned to discontinue the manufacture and sale of its HD DVD players, effectively ceding the market to Blu-Ray. See Press Release, Toshiba, Toshiba Announces Discontinuation of HD DVD Business (Feb. 19, 2008), available at http://www.toshiba.co.jp/about/press/2008_02/pr1903.htm.

40 Daniel F. Spulber & Christopher S. Yoo, Access to Networks: Economic and Constitutional Connections, 88 CORNELL L. REV. 885, 922 (2003) (“[A] growing number of scholars have raised the concern that network owners may be able to use interconnection (or, more accurately, the refusal to interconnect) as an anticompetitive weapon.”).

41 More precisely, the output of a network is “the use of the network’s services.” Id. at 894.

42 These costs would include any financial outlays, as well as time spent learning to operate the new technology.

43 Shelanski & Sidak, supra note __, at 9. Take, for example, Facebook’s social-networking website. The value of the code-based product is entirely dependent on the number of users in the network—and at this point in time, there are over 500 million active users. Statistics, FACEBOOK, http://www.facebook.com/press/info.php?statistics (last visited Mar. 26, 2011). Given that many users, the network’s value is very substantial, as reflected in a recent valuation (completed in preparation for Facebook’s planned 2012 IPO) placing the Facebook corporation’s value at an estimated $50 billion. Anupreeta Das, Geoffrey A. Fowler & Liz Rappaport, Facebook Sets Stage for IPO Next Year, WALL ST. J. (Jan. 6, 2011), http://online.wsj.com/article/SB10001424052748703730704576066162770600234.html. A potential rival, on the other hand, would naturally start with zero users, and would offer relatively negligible value to potential users. Since Facebook is currently not interoperable with any other social-networking websites, rivals would need some massive advantage to offer users in order to enter the market. One potential rival, “PeopleString,” actually pays users; its market share remains dwarfed by Facebook’s.
by the market leader. This holds true even if that path is not the highest-quality or most efficient possible.\textsuperscript{44}

2. Innovation-Based Rivalry

As noted above, another characteristic of the New Economy seems to be a more rapid pace of innovation was seen than in many of the industries that traditionally fell under antitrust scrutiny. This has given rise to scholars and commentators proclaiming that digital markets are driven primarily by innovation, rather than price.\textsuperscript{45} Their vision, which traces its roots directly to the writings of Joseph Schumpeter, is of a marketplace periodically dominated by innovative firms, which are in turn displaced by firms that market the next wave of technology. The core of the concept is that “the pursuit of market power is a creative and dynamic force that ‘incessantly revolutionizes the economic structure from within, incessantly destroying the old one, incessantly creating a new one.’”\textsuperscript{46} Under this view, though a firm might temporarily gain monopoly power in a market, subsequent innovation by competitors will ensure that its ability to charge supracompetitive prices will be short-lived.\textsuperscript{47} And as a result, adherents call for a reduced role of antitrust enforcement in markets that seem to thrive on innovation-based rivalry.

It is true that the advent and continuing improvement of the digital computer and the now-widespread availability of high-speed, mobile Internet access have spawned many new advances—including “products that could not, or would not, have been built before the Net. Among these we could include the dynamically generated maps with driving directions; massive translation engines . . . , and on-line dictionaries covering hundreds of languages that otherwise would not be available . . . .”\textsuperscript{48} Computing power has historically increased at such a rapid pace that a term, “Moore’s Law,” has been

\textsuperscript{44}See Shelanski & Sidak, supra note __, at 9.
\textsuperscript{45}See, e.g., Weiser, supra note 13, at 3 (“The dynamics of today’s information age have pushed economists further away from the classic, static focus on prices—which remains an important part of economics, to be sure—to a greater appreciation for the impact of innovation.”).
\textsuperscript{46}Shelanski & Sidak, supra note __, at 11 (quoting JOSEPH A. SCHUMPETER, CAPITALISM, SOCIALISM AND DEMOCRACY 83 (1942)).
\textsuperscript{47}Schumpeter also famously suggested “that large firms and monopolists may be more innovative than firms in competitive markets.” Jonathan B. Baker, Beyond Schumpeter vs. Arrow: How Antitrust Fosters Innovation, 74 ANTITRUST L.J. 575, 578 (2007). Perhaps the primary argument in favor of this proposition is that large firms and monopolists are more capable of funding research-and-development projects than are smaller firms. See id. On the other hand, as Judge Learned Hand memorably stated in the seminal Alcoa decision: “Many people believe that possession of unchallenged economic power deadens initiative, discourages thrift and depresses energy; that immunity from competition is a narcotic, and rivalry is a stimulant, to industrial progress; that the spur of constant stress is necessary to counteract an inevitable disposition to let well enough alone.” United States v. Aluminum Co. of Am., 148 F.2d 416, 427 (2d Cir. 1945).
\textsuperscript{48}LESSIG, THE FUTURE OF IDEAS, supra note __, at 122.
coined to refer to its rate of development.\textsuperscript{49} And the Internet has exponentially increased, and continues to increase, the speed with which individuals can transfer large amounts of information.\textsuperscript{50} Yet many of the goods and services that may seem “new” in fact are not—take, for example, email, which is generally perceived as a product of the 1990s, when in fact it was developed over fifty years ago.\textsuperscript{51} Many are merely digital versions of physical-based services, like the online retailing offered by big-box department stores like Nordstrom’s and Macy’s. Such “new” markets are generally not characterized by rapid rates of market-shifting innovation;\textsuperscript{52} their business models are not much different from the mail-order businesses that advertise through physical catalogs and have existed for over a century.

Further, it is dangerous to assume based on past innovation in a market that that market will continue to be characterized by rapid innovation. Take the telephone as an example: although it was rapidly improved and implemented immediately following its invention in 1876, the basic, underlying technology then remained static for decades. And it is, of course, never certain that even innovative rivals will unseat a dominant firm in a network market—giants like Facebook, for example, have yet to be dethroned.\textsuperscript{53} That is particularly true where the market leader refuses to allow interoperability, for an innovation may not be enough to tempt users away from the largest existing network (and the firm that controls it). Finally, “the existing body of theoretical and empirical literature on the relationship between competition and innovation ‘fails to provide general support for the Schumpeterian hypothesis that monopoly promotes either investment in research and development or the output of innovation’ . . . .”\textsuperscript{54} Given all of this, it is not at all certain that the monopolies created in digital product markets will be fleeting or quickly destroyed by subsequent innovations. Thus, Schumpeterian tenets alone—which would call for antitrust enforcement to play a limited role in markets characterized by

\textsuperscript{49} INTEL, \textsc{Moore’s Law 1} (2005), ftp://download.intel.com/museum/Moores_Law/Printed_Materials/Moores_Law_2pg.pdf.

\textsuperscript{50} See generally Christopher S. Yoo, \textit{The Changing Patterns of Internet Usage}, 63 Fed. Comm. L.J. 67, 68 (2010) (“[The Internet] has revolutionized the way people communicate with one another and obtain information . . . .”).

\textsuperscript{53} Indeed, some predict that, given (1) the extremely strong positive network externalities that characterize social-networking websites, and (2) the fact that Facebook has hit a “critical mass” of users, “Facebook isn’t going to go away anytime soon.” Farhad Manjoo, \textit{Is Facebook a Fad? What Social Networks Will Look Like in Five Years}, SLATE (Mar. 31, 2011), www.slate.com/id/2290039.

\textsuperscript{54} Manne & Wright, \textit{supra} note 16, at 166 (quoting Richard J. Gilbert, \textit{Competition and Innovation}, in 1 ISSUES IN COMPETITION LAW AND POLICY 600 (W. Dale Collins ed., 2008)).
relatively rapid innovation—cannot, and should not, dictate the degree of antitrust’s involvement in assessing product design and redesign in new-economy markets.\textsuperscript{55}

B. Antitrust Harm in Code-Based Product Markets

Though the new digital product markets on the whole appear to be characterized by a relatively rapid rate of innovation, they still allow the potential for—and sometimes even uniquely incentivize—anticompetitive behavior. As noted above, digital product markets tend to be characterized by substantial positive network externalities, whether direct or indirect.\textsuperscript{56} The potential to capture monopoly profits by becoming the dominant firm in a network market may engender a “race to gain and to maintain dominance”—one that provides “motive[] to engage in anticompetitive conduct.”\textsuperscript{57} And those monopoly profits may be more substantial and enduring than would be possible in other industries, given the barrier to entry created by a large, locked-in network of users. Indeed, a “trend to monopoly occurs as a result of the ‘network effects’ present in most high-technology markets.”\textsuperscript{58}

High-technology firms also tend to face different cost and profit structures that may encourage them to pursue monopolization through anticompetitive conduct. Digital products can be reproduced extremely cheaply, often with marginal costs approaching zero. Firms’ fixed costs, on the other hand, tend to be relatively high.\textsuperscript{59} Thus, firms that compete in digital product markets “have a substantial incentive to engage in conduct that will artificially extend the duration of their market power.”\textsuperscript{60}

As to the harm that can be inflicted by anticompetitive behavior in digital, code-based product markets, the governing principles are much the same as in other industries. A dominant firm might, for example, engage in tying practices, which can cause harm through either foreclosure of rivals\textsuperscript{61} or “leveraging”—extraction of overcharges from

\textsuperscript{55} Cf. Thomas M. Lenard, \textit{Introduction and Overview, in COMPETITION, INNOVATION AND THE MICROSOFT MONOPOLY: ANTITRUST IN THE DIGITAL MARKETPLACE} 3 (Jeffrey A. Eisenach & Thomas M. Lenard eds., 1999) (“The notion that rapid innovation, \textit{per se}, makes the market for software immune from anticompetitive conduct and/or monopolization is simplistic and misleading.”).

\textsuperscript{56} See \textit{supra} notes 3 and accompanying text.

\textsuperscript{57} Shelanski & Sidak, \textit{supra} note 3, at 9; see also 3B AREEDA & HOVENKAMP, \textit{supra} note 2, ¶ 776c, at 297 (“[N]etwork status may increase both the incentive and the opportunities for certain kinds of anticompetitive behavior.”).

\textsuperscript{58} Thomas A. Piraino, Jr., \textit{A Proposed Antitrust Approach to High Technology Competition}, 44 WM. & MARY L. REV. 65, 75 (2002).

\textsuperscript{59} See Posner, \textit{Antitrust in the New Economy, supra} note 2, at 926–27 (“Intellectual property is characterized by heavy fixed costs relative to marginal costs. It is often very expensive to create, but once it is created, the cost of making additional copies is low, dramatically so in the case of software . . . .”).

\textsuperscript{60} Piraino, \textit{supra} note 58, at 95–96.

\textsuperscript{61} See Hovenkamp & Hovenkamp, \textit{supra} note 5, at 926. “Foreclosure occurs when a tie ousts or unreasonably limits the opportunities of rivals, typically in the tied product market.” \textit{Id.} at 927.
customers. Or it might engage in predatory pricing, again foreclosing rivals (and ultimately extracting overcharges, though in the short run consumers actually benefit from the artificially low prices). And (most relevantly for purposes of this paper) “because the users of networks place a premium on compatibility, a dominant firm can exclude rivals anticompetitively by engineering incompatibilities between the dominant product and the product offered by rivals.” Thus, firms may be uniquely incentivized to create a closed network (and reap monopoly profits if that network dominates the market) by denying interoperability through design changes—as Microsoft attempted to do by steering users of its OS away from Netscape’s Navigator browser.

While the governing principles of harm are similar, the means that predatory firms have at their disposal have changed. The possibilities offered by digital product design open up a new range of anticompetitive strategies, as demonstrated by the allegations in the FTC’s complaint against Intel. As digital technology continues to evolve, new avenues for design-related anticompetitive behavior will continue to develop.

III. Anticompetitive Product (Re)design in Code-Based Product Markets

As noted above, the advent of the digital computer and widespread availability of Internet access has given rise to new industries—what some have called the “New Economy.” Importantly, the primary product created by the participants in these industries is constructed from computer code, instead of the physical materials that characterized more traditional industries. Even companies selling physical goods online, like the big-box department stores mentioned above, are offering a product that consists at least in part of the ease of use and speed of transactions allowed by code-based programs. The variety of code-based products offered today is mind-boggling. From personal-use entertainment (e.g., digitized music, film, and literature, as well as video games) to educational software, to productivity-enhancing programs like word processors and spreadsheet programs, to social-networking websites—all are intangible, code-based products. Thus, understanding the implications of code-based product design and

66 See supra notes __ and accompanying text.
67 See Posner, Antitrust in the New Economy, supra note __, at 926 (“A key to understanding these industries is that, with the partial exception of communications equipment, their principal output is intellectual property, namely computer code, rather than physical goods.”).
68 Cf. id. (stating that “Internet-based businesses, even those that sell physical products, such as groceries and books,” are offering a service that “is a function to a large extent both of the sophistication of the business’s computer software and of its trademarks and copyrights”).
69 See generally J.B. Dixit, COMPUTER PROGRAMMING 26–27 (2d ed. 2007) (describing some of the different types of software available).
redesign is crucial to understanding these new industries and markets—and the ways in which dominant market participants can engage in anticompetitive design changes.

A. Design and Redesign: Computer Programming and Software Updating

1. The Nature of Computer Code and the Products It Underlies

Computer code can be broadly divided into “source code” and “object code.” “Source code” generally refers to the text produced by a human computer programmer, written in a programming language.70 “Object code” (or “machine code”) refers to the binary data that a computer actually executes; it is unreadable by humans.71 Programming languages vary in their level of abstraction from machine code.72 Thus, at low levels of abstraction, code is much closer to machine code than to human language; conversely, high-level languages tend to be easier to understand and use.73 As a result, the more abstract (i.e., high-level) a language is, the fewer technical details the programmer must remember and input—but the less efficiently the resulting program tends to run. Low-level languages, on the other hand, tend to allow efficient programming, a necessity where computational ability and speed are of high importance.74

The source code that underlies computer programs is written line by line, not necessarily as a cohesive whole—what looks to the untrained eye like a paragraph-length section may actually contain multiple sections of code that do not relate to each other.75 Frequently, programmers will begin by setting out definitions of variables and functions that will be used throughout the program. The remainder of the program will consist of sections of code that perform certain tasks,76 referring back to the internally defined variables and functions (and sometimes to each other). Thus, a programmer may be able to look at a single section of code and explain its immediate function, though it may require a more holistic understanding of the program to explain that function fully if that section is highly interrelated to other sections. On the other end of the spectrum, however, the purpose and functionality of a single section of code that is relatively less interrelated to other sections may be much more readily apparent.

71 Thus, digital computers process “digital” data—i.e., binary code. Id. at 2.
73 The lowest-level programming language is known as “assembly language.” See id.
74 Id. (“[I]f you need speed and/or compactness above all else, Assembly is the solution.”).
75 In fact, though it is not common, a single program may be written in different programming languages.
76 While a smaller program may draw from a single source-code file, most larger programs reference hundreds or thousands of separate source-code files. See Source Code, supra note 70.
Source code by itself cannot be read by a computer. Thus, once written by a programmer, high-level source code must be run through a compiler, a software program (itself consisting of code) that translates an entire program written in human-readable source code into a program written in machine-readable object code. The resulting product is a file executable by computers. Consequently, code-based products are generally distributed to users solely in the form of object, rather than source, code. Although the primary method of distributing these code-based products to users was once physical disks, distribution via the Internet has become increasingly prevalent. Video games, for instance, were once sold primarily in brick-and-mortar stores like GameStop on physical disks. The same games, however, are now sold (by some of the same firms, including GameStop) via websites that allow users to download the files directly to their computers’ hard drives.

2. Redesigning Code-Based Products

Like any other product, a software program is frequently not perfect, particularly in its early iterations. Software programs, however, can also be retroactively “redesigned” through software updates. These updates are typically distributed to users in the form of executable files written in object code that modify the software program itself. Software can be, and is, redesigned via updates for myriad reasons—from adding new features, to fixing “bugs” in the software that cause it to run poorly or inefficiently, to ensuring security from malicious hackers and viruses, to external factors like an upgrade to a new OS. As the In re Intel and Microsoft III cases demonstrate, however, software design can also be anticompetitive—and software redesign through updating is no exception.

---

77 See Georges Ifrah, The Universal History of Computing: From the Abacus to the Quantum Computer 309 (E.F. Harding trans., 2001) (“The written programme is then interpreted by a reader connected to the computer, its contents being translated into the machine’s internal language . . . . The computer may then carry out the programme . . . .”).
78 Cf. id. (using the term “reader” interchangeably with “compiler”).
79 An “interpreter” is a program (somewhat similar to a compiler) that instead translates source code into object code one statement at a time, then immediately executes that statement. Dixit, supra note __, at 28.
80 See, e.g., Downloads – Buy New and Downloadable PC Games, GameStop, http://www.gamestop.com/downloads (last visited Mar. 30, 2011). And the future may be in the “cloud”—already, the technology exists for (among other things) playing video games on remote servers, making the physical platform on which a game is played largely irrelevant to individual users’ enjoyment of it.
82 Updates do so in one of two ways: they either (1) completely replace part of the object code underlying the program, or (2) simply insert additional object code into the program’s object code.
83 See ITOMIC, supra note __ (discussing the primary reasons software updates are issued).
84 See supra notes __, and accompanying text.
3. The Apple iPod iTunes Antitrust Litigation

On January 3, 2005, a class action suit was filed against Apple Computer, Inc., alleging (among other things\(^{85}\)) that Apple had violated § 2 of the Sherman Act.\(^{86}\) The plaintiffs’ theory—refined over the course of multiple amended complaints (and several years)—came to rest on product-design allegations. In 2001, Apple introduced a portable, digital music player, the now-ubiquitous “iPod.” It allegedly subsequently obtained monopoly power in the portable digital-audio player market.\(^{87}\) It also introduced “iTunes,” a software program (freely downloadable from Apple’s website) that is compatible with the iPod, that allowed computer users to catalog and organize their digital music libraries.\(^{88}\) The iPod initially could play only “unprotected” song files in .mp3 format.\(^{89}\) “Unprotected” formats contain no restrictions on customers’ use of the files; “protected” formats contain digital-rights-management (“DRM”) software that restricts end uses. Subsequently, however, Apple launched the “iTunes Music Store,” an online music store that allows customers to purchase and download a wide variety of songs and albums.\(^{90}\) With the iTunes Music Store, Apple was entering a new market—the market for audio-file downloads.\(^{91}\) At least according to the plaintiffs, Apple also obtained monopoly power in this market.\(^{92}\)

---

85 The plaintiffs also initially included a § 1 claim, which was subsequently dismissed. See The Apple iPod iTunes Anti-Trust Litigation, No. C 05-00037 JW, 2010 WL 2629907, at *1 (N.D. Cal. June 29, 2010) (“In its October 30 Order, the Court found that Plaintiffs failed to state a tying claim pursuant to Section 1 of the Sherman Act . . . on the ground that Plaintiffs’ allegations of a technological interrelationship between iTunes and iPods did not amount to a coercive tie.”).

87 Amended Complaint, supra note __, at 23 (“Apple has monopoly power in the Portable Digital Player Market.”).

89 The “.mp3” format uses data compression to reduce the size of CD-quality audio files, facilitating their storage and transmission. The trade-off for the more convenient file size is a (generally imperceptible) loss in audio quality.

90 Amended Complaint, supra note __, at 10.

91 This product market might more properly include only non-copyright-infringing audio-file-downloads—a robust market for pirated music (and films) existed then as it does now, though there may be relatively low cross-elasticity of demand for the two types of files, given the potential liability entailed by downloading pirated files. See generally Piracy: Online and on the Street, RIAA, http://www.riaa.com/physicalpiracy.php (last visited Mar. 30, 2011) (discussing what the Recording Industry Association of America terms “music theft”). At least according to the RIAA (far from an unbiased source), during a five-year span from 2004 to 2009, “approximately 30 billion songs were illegally downloaded on file-sharing networks.” For Students Doing Reports, RIAA, http://www.riaa.com/faq.php (last visited Mar. 30, 2011).

92 See Amended Complaint, supra note __, at 11–12 (stating that Apple obtained a 92% market share in the “Audio Download Market” as defined by the plaintiffs).
a. The Audio-File Market

The audio-file market is a complex and, at least to some degree, a network market exhibiting both direct and indirect positive network externalities. Taking into account the seemingly inevitable copyright infringement that accompanies downloading audio files in unprotected file formats, the audio-file-download market is characterized by direct positive network externalities. This is so because, when song files are sold to users in unprotected file formats, those users can then share audio files with other users, whether as a gift or in exchange for song files or other remuneration from such users—albeit in violation of the Copyright Act. Thus, increased usage by others directly increases the value of the original product to a user. The indirect positive network effects, on the other hand, arise because increased usage incentivizes sellers to increase the number of titles offered through their online stores, which in turn increases the value of audio-file players to users.

Further, the network may be open or closed, depending on whether unprotected or protected file formats are used. If audio files are distributed in an unprotected format, all firms that wish to offer files for download are generally free to do so using that format. The files themselves can be played on a variety of software programs and portable digital-audio players, and users can even download song files from each other via person-to-person file-sharing networks (again, frequently in violation of U.S. copyright laws). If, however, a firm encodes its audio files with its proprietary DRM software, it can effectively restrict consumers from playing the files on other firms’ audio players or uploading files to or downloading them from other users’ music libraries. Thus, a firm that produces both DRM-protected song files and digital-audio playback programs (whether installed on personal computers, portable digital-audio players, or both) can effectively create a closed market with which other firms’ products are not interoperable.

b. Apple Closes the Network

Initially, Apple intended to compete in an open network—in fact, it “touted the iPod’s interoperability as a selling point, and made no efforts to restrict the music that could be played on the device. Similarly, iTunes users could sync their [digital music] libraries with non-Apple devices.” According to the complaint, however, at the same time Apple launched the iTunes Music Store, it “secretly ‘updated’ the iTunes software so that iTunes and its iPod were compatible with FairPlay, Apple’s proprietary DRM.” Apple at all times refused to license FairPlay to other firms that offered digital-audio downloads. And with all of that, the pieces were now in place for Apple to close its network and strive for continued dominance in the audio-download market.

Concurrently with the introduction of the iTunes Music Store, Apple allegedly updated the iTunes software and issued a new generation of its iPod music players so that (1) the iTunes music-library program could export audio files only to iPods (not competing portable media

---

93 See generally 17 U.S.C. § 106(1) (2006) (granting to copyright owners the exclusive right “to reproduce the copyrighted work in copies or phonorecords).
94 Amended Complaint, supra note __, at 4.
95 Id. at 11.
players), and (2) iPods would accept files only from iTunes (not competing software).\textsuperscript{96} It also began selling song files encoded with FairPlay; such files could be played only via iTunes (on computers) and on iPod portable music players. Thus, Apple had effectively created a closed network—it offered song files for purchase and download through the iTunes Music Store that could be played only via its iTunes and iPod products. Meanwhile, iTunes and iPods could play only Apple’s proprietary-DRM-encoded files (not those offered by other firms).\textsuperscript{97}

Though further factual development would be needed for a more definite explanation, it seems likely that Apple was making the choice to switch to a closed network, purposely prompting the race for dominance that such decisions tend to cause.\textsuperscript{98} Such a move is a gamble—on the one hand, Apple might have chosen to instead maximize interoperability with rival music players in order to maximize sales of digital-audio files from the iTunes Music Store. But as noted above, if a closed market “tips” in favor of one firm, the resulting monopoly will be protected by the natural barrier to entry constituted by the size of the network itself, allowing the dominant firm to charge monopoly prices.\textsuperscript{99}

With a closed network in place, one that (at least according to the plaintiffs) dominated the market, Apple would rationally begin setting prices above marginal cost. In such a setting, it would be natural for the resulting profits to attract new entrants. And indeed, RealNetworks, a competitor in the audio-file-download market, announced in January 2003 that its software-based music player had become capable of playing songs bought from the iTunes Music Store.\textsuperscript{100} Subsequently, in July 2004, RealNetworks announced the release of its “Harmony” software, which allowed songs purchased from RealNetworks’ online store to play on iPods.\textsuperscript{101} Likely of greatest concern to Apple, however, was the fact that RealNetworks was now offering legal music downloads—in a file format that was fully compatible with Apple products—at prices as low as $0.49 per song, substantially undercutting Apple’s traditional price of $0.99 per song.\textsuperscript{102}

Apple responded quickly. In a press release, it stated: “We are stunned that

\textsuperscript{96} Id. at 4 (“Unbeknownst to consumers, Apple released a new generation of iPods and altered the iTunes software so that iTunes and iPods were only interoperable with each other.”).

\textsuperscript{97} This network, it should be noted, was closed more specifically only as to DRM-encoded song files—iTunes and iPods remained capable of playing unprotected .mp3-format audio files.

\textsuperscript{98} See supra notes ___ and accompanying text. Alternatively, it could be argued that Apple’s using FairPlay was an attempt to comply with the wishes of record companies, who have a strong interest in preventing music piracy. Defendant Apple’s Response Brief. Yet, as the plaintiffs’ amended complaint points out, “[t]hese companies . . . did not require Apple to limit Audio Downloads to use with Apple products. It was Apple’s choice to encode the Audio Downloads sold through iTS with its own proprietary DRM, FairPlay.” Amended Complaint, supra note __, at 11.

\textsuperscript{99} See supra notes ___ and accompanying text.

\textsuperscript{100} John Borland, RealNetworks Breaks Apple’s Hold on iPod, TECHREPUBLIC (July 26, 2004), http://www.techrepublic.com/article/realnetworks-breaks-apples-hold-on-ipod/5283479.

\textsuperscript{101} Id.

\textsuperscript{102} At least according to RealNetworks, its prices were incredibly successful in attracting customers away from Apple’s iTunes Store, even over a short period of time. “In its first three weeks of selling iPod-compatible music files, RealNetworks sold approximately three million music files,” which equated to about 10% of the market shifting from Apple to RealNetworks. Amended Complaint, supra note __, at __.
RealNetworks has adopted the tactics and ethics of a hacker to break into the iPod, and we are investigating the implications of their actions under the DMCA and other laws. Beyond merely investigating the copyright-law implications of RealNetworks’ actions, however, Apple also issued a veiled threat: “We strongly caution Real and their customers that when we update our iPod software from time to time it is highly likely that Real’s Harmony technology will cease to work with current and future iPods.” And Apple allegedly made good on this threat, issuing software updates to its iTunes music-library program that blocked RealNetworks and its Harmony software from any interoperability with Apple products.

According to the plaintiffs, this pattern repeated itself multiple times. “For example, in or about the beginning of 2005, a software program known as JHymn . . . was developed . . . so that Audio Downloads purchased from [the iTunes Store] could be played on . . . Apple’s iPod or any non-Apple device.” Apple, however, “immediately began issuing software updates to thwart JHymn.” It also used software updates to block similar programs from achieving interoperability with Apple products. By 2009, Apple found itself in a game of cat-and-mouse with Palm, which had programmed one of its smartphones to accept digital music files uploaded from Apple’s iTunes music-library program. For months, the two companies issued warring software updates to their respective devices—Palm would issue an update reopening connectivity; Apple would respond with an update re-blocking it.

Importantly, the plaintiffs alleged that Apple’s software updates served no procompetitive, innovative purpose. On the strength of those allegations, the district court denied Apple’s motion to dismiss the product-design § 2 claims. In a subsequent amended answer, on the other hand, Apple admitted only “that it released updates to its FairPlay

---

105 See Amended Complaint, supra note __, at __ (“True to its threat, beginning in October 2004, Apple ‘updated’ its iPod and iTunes software to prevent songs downloaded from RealNetworks’ music store from being played on iPods.”). All iTunes users were allegedly required to install the new software updates if they wished to continue to use Apple’s iTunes Store. Id. Further, Apple allegedly failed to disclose to consumers that the updates would block interoperability with RealNetworks’ products. See id.
106 Id.
107 Id.
108 See id. (identifying QTFairUse and PlayFair as additional programs targeted by Apple’s software updates).
109 See id. (referring to three separate Apple updates and two Palm updates over a three-month period, each of which either reestablished or blocked interoperability between Apple and Palm products).
110 Id. at __ (“Apple continually redesigned its software even though it admitted that doing so served no genuine antipiracy purpose.”).
111 The Apple iPod iTunes Anti-Trust Litigation, No. C 05-0037 JW, C 07-06507 JW, 2010 WL 2629907, at *4 (“The Court finds that Plaintiffs has alleged facts, which if proven true, would suffice to hold Defendant liable under Section 2 of the Sherman Act.”).
technology to, among other things, stop JHymn and other hacks that circumvented the content protection required by the [major record] labels on music purchased from the iTunes Store.”\textsuperscript{112} The inclusion of “among other things” raises—or at least does not eliminate—the possibility that Apple will allege some procompetitive justification other than merely foreclosing rivals. Thus, at least at the pleading stage, no clear answer has emerged as to whether the updates were pro- or anticompetitive (unlike, e.g., Microsoft III, where the defendant failed to identify any procompetitive justification for certain of its design-related actions).\textsuperscript{113} Yet, if the plaintiffs’ allegations are correct—and if they are susceptible of proof at trial\textsuperscript{114}—Apple may very well be (eventually) found guilty of monopolization through product redesign.\textsuperscript{115}

B. Software Updates as a Uniquely Attractive Method of Using Product Redesign to Foreclose Rivals

The facts of the Apple iPod iTunes Anti-Trust Litigation present issues unique to antitrust product-design jurisprudence. In particular, the use of software updates to quickly, cheaply, and easily—yet effectively—redesign code-based products with an eye toward closing a network, destroying interoperability to preserve a closed-network monopoly, or otherwise excluding rivals

\textsuperscript{112} Defendant Apple Inc.’s First Amended Answer and Defenses to Plaintiffs’ Amended Consolidated Complaint at ¶ 65, The Apple iPod iTunes Anti-Trust Litigation, No. C 05 00037 JW, 2010 WL 6323163 (N.D. Cal. Sept. 24, 2010).

\textsuperscript{113} Recently, the district court denied Apple’s motion for a protective order and allowed the plaintiffs to depose Apple’s CEO, Steve Jobs. The order, however, included the requirement that the deposition be limited to the subject of Apple’s anticompetitive actions toward RealNetworks. See Order Granting in Part and Denying in Part Apple, Inc.’s Motion for a Protective Order, The Apple iPod iTunes Antitrust Litigation, No. C05-0037 JW (HRL), 2011 WL 976942, at *3 (N.D. Cal. Mar. 21, 2011) (“[T]he deposition shall be limited to the topics of (a) the July 26, 2004 RealNetworks announcement [regarding Harmony], (b) the July 29, 2004 Apple Announcement in response thereto, and (c) Apple’s software updates in October 2004 that rendered the RealNetworks’s digital music files once again inoperable with iPods.”); see also Philip Elmer-DeWitt, Judge Orders Steve Jobs To Appear, FORTUNE (Mar. 22, 2011), http://tech.fortune.cnn.com/2011/03/22/judge-orders-steve-jobs-to-appear/ (detailing the events leading up to the court order, including a continuance granted so that Jobs could “focus on his health”).

\textsuperscript{114} The plaintiffs may also face difficulty in showing that Apple has monopoly power in the relevant markets, given the somewhat unfamiliar product markets the plaintiffs will need to define for their monopolization claims to succeed. See generally Philip Elmer-DeWitt, Does Apple Have a Monopoly?, FORTUNE (Feb. 16, 2011), http://tech.fortune.cnn.com/2011/02/16/does-apple-have-a-monopoly/ (“The answer to . . . whether Apple has sufficient control over a particular market for regulators to even ask whether its behavior has been abusive or coercive depends on how you define the market.”).

\textsuperscript{115} Certainly, the Apple litigation bears some resemblance to the landmark Microsoft antitrust litigation. See id. (“[I]n the months ahead . . . you will hear Apple using many of the same legal arguments Microsoft made . . .”). Both are high-technology firms that appear dominant in their core competencies—code-based product markets characterized by positive network effects—and both are unquestionably innovative.
from the market poses a distinctive threat to competition and innovation. And it is a threat that
does not implicate, or implicates less heavily, the traditional concerns with condemning product
redesigns under the antitrust laws.

One of the primary concerns with condemning product redesigns as anticompetitive is
that “in most cases if the conduct is excessively exclusionary it is also self-deterring.”116 More
specifically, it is thought that “a product innovation is extremely costly and time consuming to
develop, design, manufacture, and place on the market.”117 Further, redesigning goods merely to
make them incompatible with competitors’ products will likely cause customers to react
negatively.118 And there are “sunk” costs associated with innovation, i.e., costs that cannot be
recovered once invested.119 If negative customer response forces the firm to pull the new
product, the firm will forfeit these sunk costs; it will also incur reversal losses in switching back
to its former product.

Thus, if \( C_i > P_m - LR \),120 a rational firm will not engage in the anticompetitive, design-
related behavior. Redesigning physical products is generally fairly expensive, so \( C_i \) in such
markets is relatively high, making true anticompetitive product redesigns rare. Since innovations
have traditionally been “extremely costly,” and those costs were unrecoverable in the face of a
failed product launch, \( L \) has also been considered to be high. Additionally, firms could expect to
incur substantial reversal losses, making \( L \) still higher. Finally, expected customer resistance to
products that do not represent true innovations has made \( R \) also relatively high, further
dissuading such behavior. Therefore, the argument goes, the market itself tends to discipline
potential anticompetitive product-design decisions. The left side of the formula tends to
outweigh the right.

As an initial matter, the potential rewards of anticompetitive code-based product redesign
through software updates may frequently be greater than those of physical product design,
increasing the value of \( P_m \) in the formula above. This is so because, as noted supra, the relevant
markets tend to be characterized by positive network externalities that form a natural barrier to
entry.121 Given that, a firm that dominates a closed network market may enjoy a more stable
monopoly than would be possible in a non-network market.122

But more importantly, and more certainly, other factors in the formula are different in the
realm of digital product markets and software updates. Specifically, I contend first that \( C_i \) tends
to be lower, reducing the value that the right side of the formula must overcome in order to make

117 3B AREEDA & HOVENKAMP, supra note __, ¶ 775c, at 284.
118 See HOVENKAMP, supra note 111, at 276.
119 See Spulber & Yoo, supra note __, at 919–20 (discussing sunk costs generally and in relation
to the telecommunications industry).
120 Where \( C_i \) is the costs a firm incurs by redesigning the product and bringing the replacement to
market, \( P_m \) is the potential monopoly profits, \( L \) represents the potential losses from unrecoverable
sunk costs, reversal costs, or damages awards in antitrust suits, and \( R \) represents the risk—the
probability that the design will fail due to customers rejecting the new product or the design
being condemned under antitrust laws.
121 See supra notes __ and accompanying text.
122 Subject, of course, to the possibility that it will be “leapfrogged” by firms innovating around
its network. See supra notes __ and accompanying text (discussing the argument that the New
Economy tends to be characterized by higher rates of innovation).
an anticompetitive product redesign rational. Next, I argue that $R$ also tends to be lower, reducing the amount that usually offsets the potential of monopoly profits. Finally, I also contend that $L$ tends to be lower. Each of these features tends to make anticompetitive product redesign through software updates uniquely attractive to firms.

1. **Relatively Low Design-Related Costs to Firms: Lower $C_i$ Incentivizes Anticompetitive Product Redesigns**

As the costs to firms of developing and distributing a product redesign decrease, the attractiveness of an anticompetitive product redesign increases. The following two subparts discuss two reasons redesigning code-based products through software updates is inexpensive relative to redesigning physical products. Part IV.B.1.a explains that developing a software update tends to entail lower sunk costs than developing a new physical good, while Part IV.B.1.b explores the low distribution costs associated with issuing software updates via the Internet. Importantly, both factors tend to lower $C_i$ and, as a result, make anticompetitive product redesign more attractive to firms.

**a. Low Development Costs Relative to Physical-Product Redesign**

Redesigning code-based products through software updates generally entails low development costs relative to redesigning physical products, making it an inviting avenue for anticompetitive design-related conduct. Software can be effectively redesigned through an update—which may affect only a small part of the software program—relatively cheaply. Take, for example, the product designs at issue in some of the seminal product-design antitrust cases discussed in the following Part: a new computer system (the IBM plug-compatible cases\textsuperscript{125}), instant camera and redesigned, complementary film (\textit{Berkey Photo}\textsuperscript{126}), or skin-graft gun and redesigned replacement needles (\textit{C.R. Bard}\textsuperscript{127}). Each required a team of engineers, changes to production facilities, and substantial marketing costs. A software update, on the other hand, can be designed and produced by a single computer programmer working at a single desktop computer; at most, it requires only a team of programmers.\textsuperscript{128} Thus, the development costs of software updates tend to be lower than those entailed by redesigning physical products, lowering the value of $C_i$ in the formula above. Yet software updates can be used just as effectively to exclude rivals from a market as a physical redesign—as Apple did in issuing software updates to block interoperability with RealNetworks’ digital audio files.\textsuperscript{129}

So, while the potential rewards of code-based product design through software updates are generally greater than or similar to those of physical product design, the sunk costs of

\textsuperscript{123} See infra Part IV.B.1.
\textsuperscript{124} See infra Part IV.B.2.
\textsuperscript{125} \textit{In re IBM Peripheral EDP Devices Antitrust Litigation}, 481 F. Supp. 965, 972 (N.D. Cal. 1979).
\textsuperscript{126} \textit{Berkey Photo, Inc. v. Eastman Kodak Co.}, 603 F.2d 263 (2d Cir. 1979).
\textsuperscript{127} \textit{C.R. Bard, Inc. v. M3 Systems, Inc.}, 157 F.3d 1340 (Fed. Cir. 1998).
\textsuperscript{128} Cf. PETER SEIDEL, CODERS AT WORK: REFLECTIONS ON THE CRAFT OF PROGRAMMING 155 (discussing writing and rewriting computer code).
\textsuperscript{129} See supra notes __ and accompanying text (noting that Apple admitted to doing so).
development are relatively lower. Thus, the overall risk usually associated with a purely exclusionary physical product design is relatively higher than the risk of issuing an anticompetitive product update. And as a result, it is more likely that $C_i < P_m - LR$, making anticompetitive design decisions more likely rational—and the market less able to act as a check on exclusionary design conduct in this area.

b. Speed, Ease, and Low Costs to Firms of Online Software-Update Distribution

Like initial distribution of software,\textsuperscript{130} updating software was once a costly, time-intensive project. It generally required design and subsequent distribution of code-based program files on physical disks to consumers. Given that files typically needed to be stored on such disks to allow for transportation to end users, distribution channels were necessarily physical. And as a result, distribution was relatively slow and costly. Immediate updates for the purpose of repairing unforeseen problems with software—or for any other reason—were impossible.

Installing the updating files, at least in the early days of digital computing, also required expertise on the part of consumers, or, alternatively, required consumers to hire expert installers. In these ways, updating code-based software was fairly similar to updating the design of other physical products—take, for example, a car. Frequently, auto manufacturers design, develop, and ultimately sell a particular make and model to consumers, then discover a defect in the design months (or even years) down the road—perhaps a flaw in the vehicle’s airbag system. In order to “update” the design, the manufacturer must issue a recall announcement asking consumers to bring their vehicles to a dealer for replacement or repair of the faulty system. The manufacturer must also physically distribute the relevant replacement parts to its dealers. Consumers would then have to bring their vehicles to the dealer in order to complete the installation of the update, making the entire process quite lengthy—months, or even years—and costly to manufacturers.\textsuperscript{131}

With the advent of nearly universal access to the Internet, however, firms marketing products based on computer code were given an unprecedented, even revolutionary, distribution tool. Programmers can now write update files that a firm can distribute to users almost instantaneously, eliminating the lion’s share of the time lag inherent in physical distribution systems. Likewise, the Internet has made costs to software firms of update distribution relatively negligible—unlike, e.g., the costs an auto manufacturer would incur by shipping 14 million cruise-control switches via physical

\textsuperscript{130} See supra notes __ and accompanying text.

\textsuperscript{131} The scale of such recalls can be massive—currently, the largest auto recall in history included 14.1 million Ford vehicles that had been built with faulty cruise-control switches. The model years included were 1993–2004; Ford announced the recall in two separate announcements, one in 2008 and the other in 2009, years after the defective vehicles were sold. See Vincent Aubé, Ten Biggest Auto Recalls, MSN AUTOS, http://autos.ca.msn.com/photos/gallery.aspx?cp-documentid=22338216 (last visited Mar. 30, 2011).
distribution systems.\footnote{132 See generally id. (describing such a recall).} As a direct result, updating software through files distributed via the Internet has become an industry norm.\footnote{133 See UpdateShield 1.0: Product Overview, SCIENTIFIC, http://www.sciensoft.com/products/updateshield (last visited Apr. 7, 2011) (“Automatic software update is becoming a standard feature in many software products today.”).}

The speed and ease of distribution of software updates can also allow a firm to be more nimble in anticompetitively redesigning its products. Consider again the rapid series of updates issued by Apple to repeatedly block interoperability with Palm’s products.\footnote{134 Amended Complaint, supra note __.} Firms wishing to foreclose competition by redesigning physical products were hampered by the length of time required for the new product to reach consumers—in the meantime, competitors could be enjoying interoperability and access to the market. Redesigning software through updates, however, allows firms to respond much more rapidly to threats by rivals.

And the relatively low distribution costs associated with issuing software updates contributes to the rebalancing of the risk–reward analysis discussed above, further incentivizing anticompetitive behavior. Given low development and distribution costs, and holding constant—or, in a network market, even increasing—the potential reward of monopoly overcharges, exclusionary product redesign becomes yet more attractive to firms. Or, put another way, it is even more likely that $C_i < P_m - LR$. Again, the market acts as much less of a check in such a scenario, mitigating one primary concern with regulating anticompetitive design-related behavior.

As the risk that customers will reject product redesigns decreases, the likelihood that a firm can offset development and distribution costs by reaping monopoly profits increases. As a direct result, lower $R$ further incentivizes anticompetitive product redesigns. The next two subparts demonstrate that redesigning code-based products through software updates does, in fact, involve relatively low risk that customers will react negatively to product redesigns.

a. **Relatively Low Cost to Consumers Lowers $R$**

As shown above, redesigning code-based products through software updates entails relatively low costs to firms. Firms can and do take advantage of these low costs to offer low-cost or free updates to software users, yet ultimately make a profit. This can be done for legitimate purposes—e.g., Facebook’s constantly updated, yet free, online social-networking service. Facebook’s profit mechanism is selling advertising space to other firms; it can afford to update its software at no extra charge to users because (1) software updates are relatively inexpensive, and (2) it is profiting from selling advertising space. But it can also be done for exclusionary purposes. Take, for example, Apple issuing free updates to its iTunes music-library program and iPod portable digital-audio...
players in order to exclude RealNetworks from the market for music downloads. Assuming Apple’s iTunes Store dominated the market for legal music downloads, Apple could have issued updates for free, yet made a profit because (1) software updates are relatively inexpensive, and (2) it was prolonging its monopoly by excluding RealNetworks from the market. Where \( C_i \) is high, firms must either absorb the costs or pass them on to consumers; where it is relatively low, firms can charge consumers less for the product redesign. And that, in turn, lowers \( R \)—an element of which is the risk that consumers will reject the redesign.

Another element of cost consumers take into account in deciding whether to accept a redesigned product is the time that would be entailed by doing so. As noted above, the time required of customers to receive and install software updates has been reduced considerably by the advent of widespread Internet access and the corresponding elimination of reliance on physical distribution processes.\(^{135}\) As compared to physical goods, consumers are required to expend minimal time by accepting software redesigned through updates delivered via the Internet. This further lowers their costs, further lowering \( R \), and further increasing the probability that an anticompetitive product redesign will be profitable.

b. The Trend Toward Automatic Software Updates

Even further mitigating this concern is one final aspect of software updating in the context of ubiquitous, high-speed Internet access: the trend toward automatic software updates. As noted above, one of the arguments against antitrust regulation of product redesigns is that customers will reject new products that are not really improvements over the old.\(^{136}\) This can hold true where customers are given a meaningful choice whether to keep the old product or switch to the new. Where, e.g., a firm begins selling a new instant camera (and new complementary film), customers can make a relatively informed choice whether to keep their old cameras and buy interoperable film from rivals, or to switch to the new camera and film.

In the new era of code-based product markets and widespread, high-speed Internet access, however, “automatic” software updates are becoming increasingly prevalent.\(^{137}\) Automatic software updates are triggered by code written into software programs themselves. This code directs the users’ computers to check a certain server via the Internet for any available updates, and to download and install any and all updates that are available. So long as the users’ computers connect to the Internet at some point, no further action is needed on the part of users in order to install the updates. There are

\(^{135}\) See supra notes ___ and accompanying text.

\(^{136}\) See supra notes ___ and accompanying text.

\(^{137}\) See UpdateShield 1.0: Product Overview, SCIENSOFT, http://www.sciensoft.com/products/updateshield (last visited Apr. 7, 2011) (“Automatic software update is becoming a standard feature in many software products today.”); Tamara Wilhite, Automatic Software Updates: The Good, the Bad, and the Ugly, IIE BLOGS (Jan. 14, 2008), http://www.iienet2.org/Blogger_comment.aspx?id=11216&blogid=612 (“Automatic software updates have a number of advantages, which is why they are so frequently used in the IT world.”).
plausible procompetitive advantages to automatic, versus manual, software updates: users need not oversee the updating process, they allow for more effective and rapid virus protection, problems with software can be fixed or “patched” more rapidly (perhaps even before the user ever notices a problem), etc.\textsuperscript{138}

But automatic software updates also eliminate customers’ ability to make an informed choice as to whether they should accept the redesigned product. Customers may not have any information available to them regarding what, exactly, the software update does. In fact, they may not even be aware that an automatic software update has occurred.\textsuperscript{139} By allowing firms to count on the virtual certainty that its product redesign will be accepted by customers, automatic software updates slash $R$ dramatically, further increasing the attractiveness of an anticompetitive product redesign. Thus, one of the primary concerns with condemning product-design decisions—that excessively exclusionary design conduct is generally deterred by potential customer resistance—does not apply with much force (if at all) to code-based product redesign through software updates.

3. **Relatively Low Losses Incurred if Product Redesigns Fail: How Lower $L$ Further Incentivizes Anticompetitive Redesigns**

As discussed above, $C_i$ tends to be lower for code-based product redesign through software updates, especially for updates distributed via the Internet. Since $C_i$ takes into account sunk costs, $L$ (the total costs incurred by a firm that undertakes a failed product redesign), which similarly accounts for sunk costs, also tends to be lower in these markets. Yet redesign of software programs carries with it another unique feature that lowers $L$ even further—relatively low reversal costs.

If a firm redesigns and brings to market a new physical product, it has likely altered its assembly and packaging lines, marketing, etc., in ways that would entail significant reversal costs in the face of a failed product launch. Take, for example, the new Instamatic cameras at issue in \textit{Berkey Photo}.\textsuperscript{140} To launch the Instamatic, Kodak needed to alter its manufacturing facilities, place orders for component parts and materials, develop and begin assembling new packaging, mount a marketing campaign, and actually ship thousands of the physical cameras to brick-and-mortar stores. If the Instamatic had been a failure, Kodak would have needed to revert its production facilities to the status quo, dump its new packaging, pull promotional materials and mount a new advertising campaign touting the old product, and (depending on contractual arrangements) perhaps account for the mass of unwanted product in the hands of retailers. All of this would have added up to significant reversal costs, making $L$ high.

Conversely, imagine Apple’s exclusionary software updates had been installed by customers who, upon realizing they foreclosed interoperability with RealNetworks, began to substitute away from Apple products. Apple could quickly, easily, and above all

\textsuperscript{138} See Wilhite, \textit{supra} note ___ (noting four distinct advantages of automatic software updates).

\textsuperscript{139} And even when software updates are not entirely automatic, frequently all a customer sees is a small pop-up window asking whether to or not to “install new updates.”

\textsuperscript{140} A more detailed discussion of \textit{Berkey Photo}’s facts—and especially the Second Circuit’s reasoning behind its decision in that case—follows. \textit{See infra} Part IV.B.
cheaply reverse the design by simply issuing another update that contained commands undoing the exclusionary code functions. It would not need to revert production facilities, change packaging, alter its advertising campaign, or account for unwanted inventory at its retail stores. This scenario would hold true for almost all code-based product redesigns through online software updates. Thus, in addition to the reductive effect of relatively low sunk costs, the lower reversal costs further reduce $L$. This, in turn, increases the value of the right side of the formula, again making anticompetitive product redesigns more attractive.

C. Code-Based Product Redesign as Uniquely Susceptible to Antitrust Scrutiny

The other primary concern is that “[a]s a general matter, antitrust courts are not competent to second-guess decisions about product design.” 141 Multiple unique features of modern code-based product redesign, however, render it uniquely susceptible to antitrust scrutiny. First, redesign through software updates allows firms to make targeted design changes to products; thus, these redesigns are much less comprehensive than typical physical-product redesigns—making anticompetitive elements more conceptually separable from procompetitive innovations. Second, and similarly, sections of code perform specific functions and are separable from surrounding sections, again facilitating the ability of courts to discern between exclusionary and innovative design elements. Finally, since computer code can be configured multiple ways to perform the same function, a design change to a code-based product that creates interoperability is more likely motivated by foreclosing rivals from the market than physical-product changes.

1. Software Updates Are Conceptually Separable from the Base Product

The stereotypical allegedly anticompetitive product design (like the design decisions challenged in, e.g., the IBM plug-compatible cases or Berkey Photo) consists of introducing to the market a significantly redesigned product that renders competitors’ complementary products non-interoperable. In such situations, courts are wisely reluctant to condemn the design change—given the conceptual difficulty of separating potentially exclusionary design elements from procompetitive innovations, courts recognize the potential that using antitrust law to condemn such changes will frequently chill innovation. 142 Yet Apple was able to use software updates to redesign small segments of products already in the hands of consumers, and was able to do so with an ease and frequency that was previously unheard-of (witness the cat-and-mouse interoperability battle with Palm). 143 By delivering targeted product redesigns almost instantaneously via the Internet, Apple’s behavior highlighted the possibilities for anticompetitive product design available to firms competing in the new code-based

141 HOVENKAMP, supra note 111, at 275.
143 See supra notes ___ and accompanying text (detailing a series of redesigns made possible by online software updates that occurred over a short period of time).
product markets. Yet it also highlights one reason such redesigns are uniquely susceptible to antitrust scrutiny.

As noted above, software updates—the dominant method of redesigning software programs—do not constitute a total redesign; instead, they contain a relatively small amount of object code that alters certain functions of the base software program’s underlying code. The update code interacts with, but exists separately from, the previous code underlying the program. Not so the redesigned Instamatic and accompanying film in *Berkey Photo*—there, the court was faced with trying to separate the design elements that led to an improved product from those that made Berkey Photo’s film incompatible. Yet the very same elements performed both functions, making conceptual separation of the two a sisyphean task that the court quite rightly declined to attempt. Since the elements and functionality of a software update are relatively easily conceived of separately from the elements of the base software program affected by the update, courts are more competent to address their effects on competition than the same courts would be in the stereotypical product-design case.

2. Lines of Code Are Separable from a Software Redesign as a Whole

The objection might be raised that a software update itself may contain both innovative and anticompetitive aspects. Thus, while an update may be conceptually separable from the base software program, it does not necessarily follow that anticompetitive elements are likewise capable of being isolated. Yet recall that a software program consists of a series of functions expressed in object code. Each line or section of code performs a specific, finite function. Thus, within the code that composes a software update, specific functions are separable. If a software update serves to foreclose interoperability with a rival’s products, that non-interoperability can be traced to those certain functions. And as a result, even if a software update contains multiple design changes, the lines of code that dictate functions within the update are separable, allowing direct analysis of what those respective functions are.

3. Code Can Be Written Different Ways to Perform the Same Function

In writing the source code for a software program, a programmer first decides what functions are needed for the program to perform its intended role. She next organizes these functions into an organizational flow chart, rearranging as necessary to achieve secondary goals like allowing for efficient computing. Finally, the programmer

---

144 And the Instamatic (along with Kodacolor II film) was indeed perceived as such by consumers—they “went on to become two of the great successes of amateur photography.” HOVENKAMP, supra note 111, at 275.

145 It should be emphasized at this point that I do not take issue with the usual contention that “courts and juries are generally incapable of addressing the technical merits or anticompetitive effects on innovation.” 3B AREEDA & HOVENKAMP, supra note __, ¶ 775c, at 284 (emphasis added); see also Sidak, supra note 6 (arguing that a rule of per se legality should apply to product innovations).

146 *See supra* Part IV.A.1.
writes the source code itself.\textsuperscript{147} “This stage in the process is comparable to the novelist fleshing out the broad outline of [her] plot by crafting from words and sentences the paragraphs that convey the idea.”\textsuperscript{148} Thus, programmers constantly make choices that are frequently arbitrary—even in crafting simple calculations and formulas.\textsuperscript{149} Indeed, “in the computer field, ‘[t]here exists a virtually unlimited number of instruction sequences that would enable a programmer to construct a program which performs even the more basic algorithmic or mathematical procedures.’”\textsuperscript{150}

Given that computer code can be written multiple ways to perform the same function, it is more likely that a function that destroys interoperability was programmed and distributed in order to foreclose rivals. Alleged innovative justifications traditionally raised the possibility that a redesign was procompetitive, implicating the concern that “courts are not competent to second-guess decisions about product design”\textsuperscript{151} without unduly chilling innovation. With physical products, a plausible claim can usually be made that design choices were dictated by either functional, cost-related, or aesthetic concerns, all of which may be valued by customers.\textsuperscript{152} But with the actual writing of lines of source code, functional concerns less frequently dictate the particular expression chosen by the programmer.\textsuperscript{153} And aesthetic concerns drive decisions only to the extent that the programmer herself prefers a certain design for its aesthetic value,\textsuperscript{154} for consumers almost never see the object (let alone the source) code underlying the programs they use.\textsuperscript{155} Thus, alleged innovative justifications are much more capable of

\textsuperscript{147} See Marc T. Kretschmer, Note, Copyright Protection for Software Architecture: Just Say No!, 1988 COLUM. BUS. L. REV. 823, 825–826 (describing the general process of software development).
\textsuperscript{148} Id. at 826.
\textsuperscript{149} SAS Inst. v. S & H Computer Sys., 605 F. Supp. 816, 825 (M.D. Tenn. 1985) (“At every level, the process is characterized by choice, often made arbitrarily, and only occasionally dictated by necessity. Even in the case of simple statistical calculations, there is room for variation . . . .”).
\textsuperscript{151} HOVENKAMP, supra note 111, at 275.
\textsuperscript{152} Though courts tend to be somewhat more suspicious of claims that a redesign was a purely aesthetic improvement, it is not clear that aesthetic improvements should thus be disfavored (or at least discounted) by antitrust law. “[C]onsumer preferences are driven by aesthetic concerns as much as by concerns for lower cost, increase speed, decreased size, lightness, flexibility, and other factors.” 3B AREEDA & HOVENKAMP, supra note __, ¶ 776, at 287.
\textsuperscript{153} See SAS Inst., 605 F. Supp., at 825. Certainly, at a certain level of abstraction, generally the organizational flow-charting stage, programmers make choices based primarily on efficiency. But at the very lowest level of abstraction, the writing of lines of source code itself, multiple ways of expressing the same idea exist.
\textsuperscript{154} Cf. Anthony L. Clapes et al., Silicon Epics and Binary Bards: Determining the Proper Scope of Copyright Protection for Computer Programs, 34 UCLA L. REV. 1493, 1535 (1987) (“Not surprisingly, each programmer develops her own style of expression.”).
\textsuperscript{155} See supra note __ and accompanying text.
judicial scrutiny in code-based product markets than in traditional, physical product markets—take, for example, the United States v. Microsoft Corp. (“Microsoft III”) court’s careful dissection of the files containing the commingled Internet Explorer and Windows OS code (discussed in greater detail below).\(^{156}\) In Microsoft III, “the defendant took advantage of the fact that computer code can readily be configured in practically any fashion that programmers wish.”\(^{157}\) And, perhaps more importantly, Microsoft could offer no innovative or procompetitive justification for its choices.\(^{158}\) The fact that computer code can easily, quickly, and cheaply be configured—or reconfigured—in multiple ways further alleviates the traditional concern that courts should not second-guess product-design decisions.

IV. PRODUCT DESIGN AND TECHNOLOGICAL TIES: EARLY ANALYTICAL APPROACHES THROUGH THE DIGITAL AGE

Forging a cohesive, efficient analytical framework for addressing anticompetitive product design in code-based product markets requires first examining the somewhat tangled skein of past design-related antitrust cases. For over three decades, district and appellate courts have wrestled with how to approach claims that firms have engaged in anticompetitive, design-related behavior. A wide-ranging variety of analyses have been used, though due to the fear of stifling innovation noted above, courts have on the whole tended to be quite deferential to defendants.\(^{159}\) The prevailing school of thought runs that because (1) the market itself generally disciplines anticompetitive design-related conduct, and (2) antitrust courts are generally not competent to second-guess design decisions, condemning such conduct runs a high risk of producing false positives. Yet antitrust courts have generally been called upon to consider design conduct involving more traditional, physical products, as in the first three cases discussed below. The seminal Microsoft III marked the first major antitrust decision involving design of a computer-code-based product; it also marked a departure from the general mode of analysis used by previous antitrust courts in design-related cases.\(^{160}\) Yet default rules favoring defendants are still very much en vogue, as demonstrated by Allied Orthopedic v. Tyco,\(^{161}\) a 2010 Ninth Circuit decision also discussed infra. This Part concludes with a brief discussion of the In re Intel

\(^{156}\) See United States v. Microsoft Corp., 253 F.3d 34, 66 (2d. Cir. 2001) (“Another Government expert likewise testified that one library file, SHDOCVW.DLL, ‘is really a bundle of separate functions. It contains some functions that have to do specifically with Web browsing, and it contains some general user interface functions as well.’” (quoting the trial testimony of Edward Felten)).

\(^{157}\) HOVENKAMP, supra note 111, at 276.

\(^{158}\) See Microsoft Corp., 253 F.3d at 67.

\(^{159}\) Naturally, this defendant-friendly standard employed by most antitrust courts lowers one component of \(R\) in the formula explored above—the potential costs entailed by defending and/or losing an antitrust lawsuit.

\(^{160}\) 253 F.3d 34 (D.C. Cir. 2001).

\(^{161}\) Allied Orthopedic Appliances Inc. v. Tyco Health Care Group LP, 592 F.3d 991, 994–95 (9th Cir. 2010)
consent decree,\textsuperscript{162} also issued in 2010, as an example of the ever-expanding avenues of anticompétitive product design available to high-technology firms.

\textbf{A. The IBM Plug-Compatible Peripherals Litigation}

In 1964, IBM introduced its extremely successful third-generation computer systems to the nascent computer-system market.\textsuperscript{163} IBM’s resulting profits naturally attracted competitors, and in the late 1960s, “several companies began marketing copies of IBM’s tapes, disks and printers, which were ‘plug-compatible’ with IBM CPUs.”\textsuperscript{164} These plug-compatible devices were not only perfect substitutes for IBM peripherals, they were much cheaper.\textsuperscript{165} In response, IBM introduced the “370” system, which used a “new and improved peripheral[]” design that was incompatible with the plug-compatible manufacturers’ existing designs.\textsuperscript{166}

Several of the plug-compatible manufacturers (“PCMs”) sued IBM under §§ 1 and 2 of the Sherman Act, alleging (among other theories) that IBM’s new product design was anticompetitive. The theory was fairly straightforward: “a monopolist could utilize the design of its own product to maintain market control or to gain a competitive advantage.”\textsuperscript{167} More specifically, it was essentially a “technological tie-in” theory—IBM was forcing customers of its computer systems to also buy its peripherals.

The courts addressing these cases set forth some of the foundational principles that have generally been reflected in subsequent antitrust jurisprudence considering the legality of product designs. Primary among these was concern for preserving incentives to innovate. As the district court deciding the suit brought by Transamerica put it, “[E]quipment design can have pro-competitive as well as anticompetitive aspects. Truly new and innovative products are to be encouraged, and are an important part of the competitive process.”\textsuperscript{168} Taken to the extreme, this concern can result in a standard like the one employed by the \textit{ILC Peripherals Leasing Corp.} court, which reasoned that if expert testimony so much as differs on a design’s legitimacy, the design is irrebuttably presumed legal.\textsuperscript{169} Yet deciding on a more appropriate standard proved

\textsuperscript{163} \textit{In re IBM Peripheral EDP Devices Antitrust Litigation}, 481 F. Supp. 965, 972 (N.D. Cal. 1979).
\textsuperscript{164} \textit{Id.} at 973.
\textsuperscript{165} \textit{Id.} (“A user could simply unplug the IBM peripheral, substitute the cheaper copy, and plug it into the IBM CPU.”).
\textsuperscript{166} \textit{Id.} at 972.
\textsuperscript{167} \textit{Id.} at 1002.
\textsuperscript{168} \textit{Id.} at 1003. Similarly, the district court in \textit{Telex Corp. v. IBM Corp.} stated, “Nor should the court unnecessarily involve itself in the task of the administration of . . . product designs and technological applications or other functions . . . .” 367 F. Supp. 258, 356 (N.D. Okla. 1973), rev’d, 510 F.2d 894 (10th Cir. 1975). Notably, that court issued a decree enjoining IBM to release upon request “at the time of first customer shipment of an IBM CPU or its channel, information describing the design of the electronic interface for such product.” \textit{Id.}
\textsuperscript{169} \textit{ILC Peripherals Leasing Corp. v. IBM Corp.}, 458 F. Supp. 423, 439 (N.D. Cal. 1979) (“Where there is a difference of opinion as to the advantages of two alternatives which can both be defended from an engineering standpoint, the court will not allow itself to be enmeshed ‘in a
difficult. The opposite extreme, per se illegality for product bundling or redesigns that have the effect of foreclosing rivals’ interoperability, holds the obvious likelihood of unduly chilling competition through innovation.

The courts generally disposed of the § 1 “tying” claims by holding either that the separate-products requirement was not met or that the design yielded “facially plausible benefits.” As to the § 2 monopolization claims, the courts generally found that the redesigned product was technologically superior, and thus was not “unreasonably restrictive of competition.” Some imprecisely formulated the standard as “reasonableness”—as the Ninth Circuit put it, the “reasonableness” of IBM’s behavior precluded finding an antitrust violation.

B. Berkey Photo, Inc. v. Eastman Kodak Co.

Around the same time the protracted IBM antitrust litigation was wending its way through the court system, Berkey Photo brought a somewhat similar claim against Eastman Kodak under § 2 of the Sherman Act. Both companies manufactured still cameras targeted at amateur photographers, although Kodak’s market share far outstripped Berkey Photo’s. A giant in the field at the time, Kodak had gained its position through aggressive innovations that were exceedingly well-received by consumers. Berkey Photo manufactured cameras and film...
that were interoperable with Kodak’s products.\textsuperscript{177} Kodak, however, unveiled a new system, the 110 Instamatic camera and Kodacolor II film. The camera was smaller and more convenient than its predecessors and was, by all measures, a “dramatic success.”\textsuperscript{178} It was also incompatible with Berkey Photo’s products.

Berkey’s claims included a product-design theory—that Kodak hastily launched the new products together in order to exclude Berkey Photo from the camera market.\textsuperscript{179} At the trial-court level, Kodak had contended that introducing new products must “as a matter of law” be immune from attack under the antitrust laws.\textsuperscript{180} The trial court rightly rejected this argument, reasoning that product introductions, like other ordinarily legal business decisions, may in the right circumstances be anticompetitive.\textsuperscript{181} Yet it declined to enumerate the proper analysis. On appeal, the Second Circuit held that even though there was evidence that Kodacolor II was inferior to Kodacolor X in several ways, there was also evidence that it was an improvement in at least one regard.\textsuperscript{182} The court thus held that, as a matter of law, the design and introduction were not anticompetitive, recognizing that “[p]reference is a matter of individual taste.”\textsuperscript{183}

The analysis employed by the Second Circuit was more focused than the “reasonableness” standard identified by the Ninth Circuit.\textsuperscript{184} It was also somewhat very deferential to the possibility of harming innovation. Whereas the IBM decisions generally rested on a finding that the new product was superior to the old, the Second Circuit required only evidence of some innovation or improvement—even in the face of proven disadvantages—for the product design to be held lawful. Notably, the Berkey Photo court also identified customer acceptance of the redesign as relevant to its inquiry; while such evidence may be relevant in

\textsuperscript{177} \textit{Id.} at 269 (“Other camera manufacturers, including Berkey, copied both these inventions but for several months after each introduction anyone desiring to purchase a camera in the new format was perforce remitted to Kodak.”).

\textsuperscript{178} \textit{Id.} at 278.

\textsuperscript{179} \textit{Id.} at 285. Berkey Photo also premised its claim to some degree on Kodak’s failure to give advance notice of the new film’s altered technical specifications—a claim that has been properly identified as having anti-innovative implications. \textit{See} Geoffrey A. Manne & Joshua D. Wright, \textit{Innovation and the Limits of Antitrust}, 6 J. COMPETITION L. & ÉCON. 153, 174 (2010). If firms were required to disclose novel innovations to competitors before introducing them to the market, antitrust law would essentially be “turning a novel innovation into an old hat.” \textit{Id.} The first-mover advantage that accrues to successful innovators is a crucial element in incentivizing innovative (and thus procompetitive) behavior.

\textsuperscript{180} \textit{Berkey Photo, Inc. v. Eastman Kodak Co.}, 457 F. Supp. 404, 411 (S.D.N.Y. 1979), rev’d, 603 F.2d 263 (2d Cir. 1979).

traditional product markets, for reasons discussed infra, it should bear much less heavily in design cases involving code-based products.

C. C.R. Bard, Inc. v. M3 Systems, Inc.

A less defendant-friendly analysis was used by the Federal Circuit in deciding C.R. Bard, Inc. v. M3 Systems, Inc. Like Berkey Photo and the IBM plug-compatible-peripherals litigation, C.R. Bard involved an antitrust challenge to a dominant firm’s redesign of physical products. In C.R. Bard, the eponymous firm manufactured an automated, reusable biopsy gun, as well as replacement needles for the gun. M3 Systems, a competitor, manufactured identical replacement needles that were substitutes for C.R. Bard’s needles. Bard responded by redesigning its biopsy-sampling gun so that M3 Systems’ needles were no longer interchangeable (and thus, no longer usable as substitutes for Bard’s needles). M3 Systems then sued Bard under § 2, basing its claims on a technological tie-in theory—that Bard had “leveraged its monopoly power in the guns to obtain a competitive advantage in replacement needles by modifying its gun to accept only Bard needles.”

On appeal, the Federal Circuit opened its analysis of the jury’s antitrust verdicts by identifying a standard that seemed to hinge on intent. As Judge Bryson put it, “M3 was required to prove that Bard made a change in its Biopty gun for predatory reasons, i.e., for the purpose of injuring competitors in the replacement needle market, rather than for improving the operation of the gun.” To support this, the Federal Circuit decision cited one of the IBM plug-compatible decisions discussed above. Yet there, the district court had merely identified two hypothetical situations in which a monopolist redesigned a product with the sole “purpose and effect” of foreclosing rivals, emphasizing the point that it was not thereby attempting to announce an analytical framework. The heavy focus on intent, then, represented a novel approach to product-design analysis.

On route to ultimately affirming the jury’s finding of a § 2 violation, the appellate decision admitted that at least some evidence had been adduced at trial to the effect that Bard had

193 Id.
194 In re IBM Peripheral EDP Devices Antitrust Litig., 481 F. Supp. at 1002–03.
195 Id. at 1003 (“It is more difficult to formulate a legal standard for design conduct than it is to imagine clearly illegal situations.”).
modified its gun to facilitate loading and unloading of needles—a procompetitive innovation.\textsuperscript{196} Yet the Federal Circuit pointed out that “there was substantial evidence that Bard’s real reasons for modifying the gun were to raise the cost of entry to potential makers of replacement needles, to make doctors apprehensive about using non-Bard needles, and to preclude the use of ‘copycat’ needles.”\textsuperscript{197} Thus, the court held that a jury could reasonably have found that the redesign was anticompetitive.\textsuperscript{198}

Like the record before the Second Circuit in \textit{Berkey Photo}, the record in \textit{C.R. Bard} contained conflicting evidence as to whether the product design constituted an overall innovation. Yet the Second Circuit held that in such cases the design is not anticompetitive as a matter of law. The Federal Circuit in \textit{C.R. Bard}, on the other hand, held that such cases may, at the very least, go to the jury.

D. \textit{United States v. Microsoft Corp.}

In the D.C. Circuit’s 2001 decision in the Microsoft antitrust litigation (often referred to as “\textit{Microsoft III}”), one area of Microsoft’s challenged conduct involved the integration of Internet Explorer and the Windows operating system (“OS”).\textsuperscript{199} Microsoft primarily achieved this integration via three means: (1) excluding the Internet Explorer programs from the Windows OS’s “Add/Remove Programs” function; (2) programming Windows such that, when users chose to set Internet browsers other than Internet Explorer as their default browsers, Windows sometimes overrode that choice; and (3) commingling Internet Explorer’s code with Windows code, “so that any attempt to delete the files containing IE would, at the same time, cripple the operating system.”\textsuperscript{200} These tactics, it was alleged, were designed to deter OEMs and consumers

\textsuperscript{196} \textit{C.R. Bard, Inc.}, 157 F.3d at 1382 (“Bard contended at trial that it modified its Biopty gun to make it easier to load and unload . . . .”).
\textsuperscript{197} \textit{Id.}
\textsuperscript{198} It has been urged that this was an example of the court using (if implicitly) a “balancing test” to determine whether a product redesign was, on the whole, anticompetitive. \textit{See} Jonathan Jacobson, Scott Sher & Edward Holman, \textit{Predatory Innovation: An Analysis of Allied Orthopedic v. Tyco in the Context of Section 2 Jurisprudence}, 23 LOY. CONSUMER L. REV. 1, 13 (2010) (“Although the Bard court did not articulate a ‘balancing test’ for determining whether such conduct violated the antitrust laws, the decision squarely focused on whether, on balance, Bard’s conduct would harm customers, even though it was undisputed that the ‘innovation’ did marginally improve the Bard product.”). It must be remembered, however, that the Bard court was merely deciding whether there was sufficient evidence to support the jury’s finding that the antitrust defendant had engaged in exclusionary conduct—a decision that falls under the “clearly erroneous” standard of review. Rather than balancing, then, the Federal Circuit was concerned merely with whether the jury’s decision was clearly incorrect. Further, recall that the Federal Circuit’s analysis began with the premise that product-design liability turns on a firm’s purpose. \textit{See supra} note __ and accompanying text. As a result, if the court was engaged in any balancing, it was not looking to the redesign’s anticompetitive or procompetitive effects; rather, it was considering Bard’s purpose in redesigning the gun and replacement needles.
\textsuperscript{199} \textit{United States v. Microsoft Corp.}, 253 F.3d 34, 63 (D.C. Cir. 2001).
\textsuperscript{200} \textit{Id.} at 64–65.
from using different Internet browsers, particularly Netscape Navigator,\footnote{Id. at 63.} which could perform basic OS functions (thus threatening Microsoft’s OS monopoly). Thus, while it bore some resemblance to more traditional technological-tying claims, the United States’ allegations were more complex than a simple tie-in theory. The district court found them convincing and held that Windows had thereby violated § 2 of the Sherman Act.\footnote{United States v. Microsoft Corp., 87 F. Supp. 2d 30, 44 (D.D.C. 2000) (“[T]he predatory nature of [Microsoft’s] conduct compels the Court to hold Microsoft liable under § 2 of the Sherman Act.”).}

Like the Federal Circuit in \textit{C.R. Bard}, the D.C. Circuit’s \textit{Microsoft III} decision was relatively less deferential to the possibility of deterring innovation.\footnote{The D.C. Circuit began by recognizing the concern for avoiding undue deterrence to innovation that animates much of the product-design jurisprudence. 253 F.3d at 65 (“In a competitive market, firms routinely innovate in the hope of appealing to consumers, sometimes in the process making their products incompatible with those of rivals; the imposition of liability when a monopolist does the same thing will inevitably deter a certain amount of innovation.”). It quickly went on to state, however, that “[j]udicial deference to product innovation . . . does not mean that a monopolist’s product design decisions are per se lawful.” \textit{Id.} at 65.} Rather, it applied a more traditional § 2 analysis that used burden-shifting and (somewhat controversially) a “balancing” inquiry. In analyzing the three instances of conduct set forth above, the D.C. Circuit stated that the initial burden rests on the plaintiff to show that the defendant’s conduct caused anticompetitive effects.\footnote{\textit{Id.} at 59.} The court found that here, the United States had “plainly” made a prima facie case of anticompetitive effect.\footnote{\textit{Id.} at 66.} The court’s analysis then shifted the burden to Microsoft to show some procompetitive justification for its behavior.\footnote{\textit{Id.} at 59.} As to (1) and (3), it held that Microsoft failed to show that the conduct served any purpose other than maintaining its monopoly on the OS market.\footnote{\textit{Id.} at 67.} As to (2), the court held that Microsoft alleged “valid technical reasons” for its actions.\footnote{\textit{Id.} (internal quotation marks omitted).} As a result, the burden shifted back to the United States to rebut the justification and show “that the anticompetitive effect of the challenged action outweighs it.”\footnote{\textit{Id.}} And since no rebuttal was offered, the D.C. Circuit held this aspect of Microsoft’s design-related conduct to be legal.\footnote{Conversely, “[t]he IBM cases of the 1970s all concerned computer hardware.” Heiner, \textit{supra} note \_, at 126.}

Notably, the \textit{Microsoft III} product-design claims dealt with software products, making the D.C. Circuit’s holding the first major decision on potentially anticompetitive software design.\footnote{Microsoft III, then, presented the first example of an antitrust court examining expert testimony on computer-code-based products, and the D.C. Circuit’s seminal opinion reflects}
some of the unique aspects of such products. Unlike, e.g., the Kodacolor II film under discussion in Berkey Photo, the code underlying Internet Explorer was capable of dissection into and analysis of separate functions, allowing the court more freedom to analyze anticompetitive aspects of its design.

E. Allied Orthopedic Appliances, Inc. v. Tyco Health Care Group LP

In Allied Orthopedic, the defendant, Tyco Healthcare Group LP, was a dominant manufacturer of its patented pulse-oximetry systems. Anticipating that the expiration of its patent would allow for a flood of generic entries, Tyco drew up a new design for its monitor-and-sensor system that moved the system’s digital memory chip from the monitor to the sensor, making generic sensors incompatible. Allied Orthopedic, a competitor that had planned to begin manufacturing compatible generic sensors, sued Tyco on a theory resembling a technology-tying claim. The design decision, however, also “allowed Tyco to add new features” to the sensors and reduced the switching costs incurred when customers decided to adopt a new type of sensor—which, the Ninth Circuit reasoned, in turn facilitated innovation in the sensor product market. In weighing the merits of the plaintiff’s claim, the court emphasized that “[a]s a general rule, courts are properly very skeptical about claims that competition has been harmed by a dominant firm’s product design changes.” It then rightly noted that product-design changes are not categorically immune from scrutiny under antitrust laws. Strongly departing from the D.C. Circuit’s Microsoft III decision, the Allied Orthopedic court eliminated the third step of the D.C. Circuit’s analysis, the “balancing” of procompetitive benefits and anticompetitive harm. As the Ninth Circuit put it:

There is no room in this analysis for balancing the benefits or worth of a product improvement against its anticompetitive effects. If a monopolist’s design change is an improvement, it is “necessarily tolerated by the antitrust laws” . . . .

---

212 The Microsoft III decision has been called “the seminal decision with regard to claims of anticompetitive product design.” See Jacobson et al., supra note __, at 21. While this perhaps overstates the case’s significance, the decision has been heavily discussed by other courts, antitrust enforcers, and legal scholars—it has been cited over 3000 times.

213 See Microsoft Corp., 253 F.3d at 66 (“Another Government expert likewise testified that one library file, SHDOCVW.DLL, ‘is really a bundle of separate functions. It contains some functions that have to do specifically with Web browsing, and it contains some general user interface functions as well.’” (quoting the trial testimony of Edward Felten)).

To weigh the benefits of an improved product design against the resulting injuries to competitors is not just unwise, it is unadministrable. There are no criteria that courts can use to calculate the “right” amount of innovation, which would maximize social gains and minimize competitive injury.\textsuperscript{220}

Given that it was “undisputed” that Tyco’s redesigned sensor allowed for some improvements, the court’s rubric naturally dictated that the product redesign did not violate the Sherman Act.\textsuperscript{221} This forceful holding led some scholars to characterize it as having established a per se rule shielding product redesign from antitrust scrutiny.\textsuperscript{222} While this is likely overstating the Ninth Circuit’s position to some degree, it is not too far off the mark. The \textit{Allied Orthopedic} analysis would presumably still allow a court to find an antitrust violation in a situation like, e.g., \textit{Microsoft III}, where the defendant could offer no procompetitive justification for its behavior. The analysis would, however, likely immunize the behavior condemned in \textit{C.R. Bard}, where the defendant produced evidence at trial that its redesign created at least some product improvements.\textsuperscript{223}

\textbf{F. \textit{In re Intel}}

On December 16, 2009, the Federal Trade Commission filed a complaint against Intel Corporation, alleging that it had violated § 5 of the FTC Act,\textsuperscript{224} which bans “[u]nfair methods of competition in or affecting commerce.”\textsuperscript{225} In the \textit{Intel} complaint, the FTC charged Intel with anticompetitively redesigning and selling its “compiler” software.\textsuperscript{226} “Compilers” consist of code-based software that serves a sort of translating function—they convert source code (written by human programmers) into object code (binary that

\end{footnotesize}
can be run through a “linker” utility that combines it into an executable program). The Commission alleged that Intel deliberately programmed its compilers so that they output software programs that ran more slowly on computers with non-Intel CPUs than on those with Intel CPUs. This, in turn, would cause consumers to perceive non-Intel CPUs (such as those produced by AMD, Intel’s main rival) as inferior to Intel CPUs. According to the FTC, this conduct had no procompetitive justification. The complaint also alleged that Intel initially encouraged manufacturers of graphics processing units (“GPUs”) to innovate based on Intel’s CPU platform. This interoperability was made possible by Intel’s use of open interfaces between its CPUs and chipsets. Yet after perceiving increasingly sophisticated GPUs as a threat to its dominant position in the CPU market, Intel “selectively cut off or hindered” interoperability.

Intel agreed to a consent decree on July 28, 2010; the FTC issued its decree on October 29, 2010. As to the GPU-interoperability issue specifically, the decree required that Intel refrain from designing any of its interfaces so as to intentionally make any competitors’ GPUs non-interoperable with Intel’s CPUs. And as to the product-design claims generally, the consent decree required that Intel “not make any engineering or design change” to its products if the change “(1) degrades the performance of a . . . [p]roduct sold by a competitor of [Intel] and (2) does not provide an actual benefit” to the Intel product. The decree further put the burden of showing such a benefit on Intel.

Interestingly, the FTC explained in a Notice accompanying the proposed consent agreement that merely showing “actual benefits” would be sufficient. Thus, the decree did not contemplate any sort of “balancing” of anticompetitive harms and procompetitive benefits. Yet the Notice went on to state that “[a] balancing test would be appropriate in a legal challenge to an Intel design change under Section 5 of the FTC Act or Section 2 of the Sherman Act.”

Like Microsoft III (and unlike the other product-design cases discussed here), *In re Intel* dealt with software design. And software is essentially a code-based, intangible product, rather than physical hardware like camera film, biopsy-gun replacement needles, or even the peripherals in the IBM plug-compatible cases. While it would be overreaching to infer too much from Intel’s entering into a consent decree, rather than having been found guilty of an antitrust violation, *In re Intel* at the very least demonstrates the potential that code-based products offer for anticompetitive product redesign, a potential that presents unique problems for antitrust law and its enforcers.

V. **LOOKING FORWARD: A SUGGESTED ANALYTICAL FRAMEWORK**

The Supreme Court has never decided a § 2 claim based on a theory of anticompetitive product redesign, leaving lower courts to employ the broad spectrum of analytical approaches in cases like those discussed above. As a baseline principle, all courts have recognized that “product improvement without more is protected and beyond antitrust challenge.” Beyond that, however, antitrust courts and scholars have differed on the proper approach to product-redesign liability. This Part seeks both (1) to demonstrate the flaws of past analyses as applied to design-related conduct in code-based product markets, and (2) to set forth a structured, efficient, and usable method for analyzing such conduct in the future.

A. **Defendant-Friendly Approaches Are Inappropriate**

On one end of the spectrum, some have argued that a rule of per se legality should apply to all product innovations. No court has yet gone so far, though some have come close. The *Allied Orthopedic v. Tyco* opinion, for one, has been characterized as creating such a rule. Even *Allied Orthopedic*, however, required that the defendant demonstrate at least some procompetitive justification for the redesign; if any justification is shown, the Ninth Circuit reasoned, the conduct is legal. The court in *ILC Peripherals Leasing Corp.* used a similar analysis, holding that if expert testimony so much as differs on a design’s legitimacy, the design is irrebuttably presumed legal. And the Second Circuit in *Berkey Photo* used a somewhat similar approach, holding that in the face of conflicting

---

239 3B AREEDA & HOVENKAMP, *supra* note __, ¶ 776, at 286.
240 See Sidak, *supra* note __, at 1148 (“Courts should advance from their strong presumptions of legality for technological tie-ins and acknowledge that marketing strategies for product innovations should be per se legal.”).
241 See Jacobson et al., *supra* note __, at 2 (arguing that “the Ninth Circuit’s decision in *Allied Orthopedic v. Tyco* . . . established a per se rule protecting redesign”).
242 Allied Orthopedic Appliances Inc. v. Tyco Health Care Group LP, 592 F.3d 991 (9th Cir. 2010).
243 *ILC Peripherals Leasing Corp.* v. IBM Corp., 458 F. Supp. 423, 439 (N.D. Cal. 1978) (“Where there is a difference of opinion as to the advantages of two alternatives which can both be defended from an engineering standpoint, the court will not allow itself to be enmeshed ‘in a technical inquiry into the justifiability of product innovations.’” (quoting Response of Carolina, Inc. v. Leasco Response, Inc., 537 F.2d 1307, 1330 (5th Cir. 1976))).
evidence as to whether the new product is an improvement, the conduct is legal (at least given demonstrated consumer preference for the new product). 244

What all these approaches have in common is that they place a thumb on the scale in favor of defendants, at least as compared to the generally used § 2 exclusionary-conduct inquiry,245 essentially a rule-of-reason analysis. The D.C. Circuit, in Microsoft III, set forth the general method of analysis, complete with allocations of the burden of proof. First, the burden is on the plaintiff to make a prima facie case that the defendant has engaged in monopolistic conduct (properly defined246). If the plaintiff does so, the burden then shifts to the defendant to show a procompetitive justification for the redesign. If the defendant fails to do so, the conduct is exclusionary. If, however, the defendant shows some plausible justification, the burden shifts back to the plaintiff to rebut that justification. If the plaintiff fails to do so, then the plaintiff must show that the anticompetitive harm outweighs the procompetitive justification. 247 The leading treatise takes issue with the last step, at least insofar as it seems to call for courts to engage in “balancing” of close cases—advocating instead a burden-shifting analysis that, while perhaps somewhat less defendant-friendly than the above approaches, does call for “resolv[ing] close cases in favor of the defendant.” 248 The various approaches described above, however, end the analysis and dismiss the claim as soon as the defendant shows any plausible justification for its behavior. This favorable treatment traditionally accorded defendants in this area is due largely to the concerns noted above—the fear that, because (1) the markets themselves act as a check on exclusionary product redesigns (making them quite rare), and (2) antitrust courts are generally not competent to second-guess design changes, condemning product redesigns will tend to unduly stifle innovation.

Yet, as shown above, these concerns largely dissipate in the types of markets under discussion. As to the first, the nature of code-based products and the widespread availability of high-speed Internet access have combined to make the now-standard method of redesigning these products—software updates—a uniquely attractive method of foreclosing rivals. This is so for three primary reasons: (1) low development and distribution costs,249 (2) low risk that consumers will reject redesigns,250 and (3) low

244 Berkey Photo, Inc. v. Eastman Kodak Co., 603 F.2d 263 (2d Cir. 1979).
246 There are, of course, myriad definitions of what constitutes “monopolistic conduct”; which (if any) is “correct” may vary depending on the particular facts of a case and is, at any rate, far beyond the scope of the present discussion. See generally 3 AREEDA & HOVENKAMP, supra note __, ¶ 651, at 96–109 (describing alternative definitions, their various advantages and disadvantages, and the degree to which they have been used by courts).
248 3 AREEDA & HOVENKAMP, supra note __, ¶ 651, at 122.
249 See supra Part IV.B.1.
250 See supra Part IV.B.2.
losses incurred if these product redesigns fail. Additionally, new-economy markets tend to be characterized by strong positive network externalities, which may further incentivize monopolistic behavior. Given the confluence of these factors, it is much more likely that \( C_i > P_m - LR \) in these markets. And with regards to the second concern, as shown above, the inherent and unique nature of code-based product redesign makes it uniquely susceptible to antitrust scrutiny. Given that such redesigns are more easily analyzed than traditional, physical-product redesigns, it should come as no surprise that firms may be able to offer no justification for their conduct (as occurred in Microsoft III). Alternatively, they may simply settle out of court or enter into consent decrees (as may have occurred in In re Intel). At any rate, the point is that antitrust courts no longer need to simply throw up their hands and find for defendants in design-related cases.

Since these concerns largely dissipate in these markets, the need to place a thumb on the scale in favor of defendants—i.e., the need for the inquiry to end as soon as the defendant makes any plausible claim of a procompetitive benefit—dissipates as well. And in the formula expressed above, a defendant-friendly approach lowers \( R \) by reducing the risk of antitrust liability for engaging in exclusionary, design-related conduct. Absent the usual check of market forces, such an approach even further incentivizes such conduct. Firms can and almost certainly do engage in anticompetitive design in these markets; witness Microsoft’s commingling of code, the FTC’s theory in In re Intel, or (at least according to the plaintiffs’ complaint) Apple’s exclusionary software updates. While courts are rightly reluctant in reviewing antitrust challenges to physical-product design changes, code-based product markets exhibit unique features that obviate the need for an overly defendant-friendly analysis.

B. “Actual Improvement” and “Reasonableness”

Alternative approaches used by courts in evaluating challenged product redesigns include whether the redesign constituted an “actual improvement” or whether the defendant’s conduct was “reasonable.” Both are inappropriate for somewhat similar reasons—primarily that they provide little helpful guidance to courts considering code-

---

251 See supra Part IV.B.3. Further, if the relevant market is a network market, as these markets tend to be, the incentive to engage in anticompetitive behavior even higher.

252 See supra notes ___ and accompanying text.

253 See supra Part IV.C.

258 See Calif. Comp. Prods., Inc. v. IBM Corp., 613 F.2d 727, 744 (9th Cir. 1979) (“The reasonableness of IBM’s conduct in this regard did not present a jury issue.”); accord Transamerica Comp. Co. v. IBM, 698 F.2d 1377, 1383 (9th Cir. 1983) (“[W]e affirm the district court’s ruling that the interface changes were not unreasonable.”).
based-product-redesign claims. Further, the first would tend to misdirect focus in such cases; the second is simply too vague to be of much use.

1. **“Actual Improvement”: Unfocused**

Inquiring whether a product redesign constitutes an “actual improvement” in the realm of code-based products involves too high a level of abstraction in analyzing defendants’ conduct. As an initial matter, it is geared toward scrutinizing redesigned physical products, which (as noted above) may contain inextricably interwoven design elements that serve to both improve the product and destroy interoperability with rivals’ complementary products. Thus, if the redesigned product as a whole was an improvement, it was deemed legal because courts were cautious (and likely incapable) of attempting to dissect these elements. Yet the coded functions that underlie software products are uniquely separable from the whole product, and a particular line of code is much less likely to constitute both an “actual improvement” and an exclusionary element, especially given the fact that code can be configured multiple ways to perform the same function. Thus, courts are less bound to analyze products as a whole and are more free to direct scrutiny to particularized instances of design-related conduct. Additionally, code-based products are today almost exclusively redesigned through software updates delivered via the Internet; as noted above, these updates are thus capable of isolation and separate analysis from the base product.

2. **Reasonableness: Overly Vague**

Insofar as the “reasonableness” standard is simply shorthand for antitrust’s rule-of-reason analysis, it does little harm, for “[t]he law of exclusionary practices lies at the center of antitrust’s rule of reason.” But given the complex issues at stake, the substantial harm that can be caused by exclusionary design practices (particularly in network markets), and the potential for chilling innovation that is present in all product-design and -redesign cases, it is too broad to serve as a standalone approach. Whether a change is “reasonable,” however, is an inquiry that offers little of value to

antitrust courts and, perhaps worse, provides little to no predictability for firms considering innovation.

C. Intent: Relevant, but Not Dispositive

While “intent” should be relevant to a limited degree in addressing product-design and -redesign claims in code-based product markets, it should not alone be dispositive. Recall that in *C.R. Bard*, the court characterized the inquiry as whether the plaintiff had shown that the defendant engaged in conduct “for predatory reasons, i.e., for the purpose of injuring competitors in the replacement needle market, rather than for improving the operation of the gun.” Thus, its approach seemed to hinge on subjective intent, rather than actual or likely anticompetitive effects. Other courts, including the Supreme Court, have been less than clear on the import of “intent” in monopolization cases. Yet the core concern of antitrust law is with preventing anticompetitive effects. Consequently, “[a]ntitrust appraisal of conduct depends on an understanding of its likely anticompetitive consequences as well as its possible social benefits.” The focus should be primarily directed toward effects, not intent.

And this is doubly true in the realm of product-redesign jurisprudence. A firm that redesigns its product generally has the goal of harming rivals by causing customers to substitute away from their products and to the firm’s. Yet this goal is not in itself an antitrust concern—a firm that is wildly innovative may be motivated solely by the desire to drive its rivals out of the market, yet directly and greatly increase both consumer and societal wealth through its innovations. As a result, it is frequently difficult to distinguish competitive intent from monopolistic intent. Allowing intent inquiries to inform antitrust review of design-related conduct poses a high risk of confusing the pertinent issues. Again, antitrust’s focus must be on effects; thus, subjective intent should be deemed relevant (if at all) only in ambiguous cases, where it can potentially

270 Further, “[i]n competitive markets, managers often use warlike language in referring to their rivals, even if they only plan to compete vigorously.” *Id.*
shed light on such consequences or benefits.⁷⁷¹ *C.R. Bard* may have been such a case—as noted above, in addressing a comprehensive redesign of a physical product, it is difficult (if not impossible) to conceptually separate out anticompetitive from beneficial design elements. If so, the court properly used intent as a means of discerning likely anticompetitive effects. But, as demonstrated *supra*, code-based product redesigns will rarely present a truly “ambiguous” case. Thus, in such markets, intent should rarely (if ever) be used, and intent alone should never be dispositive.

The court in *Berkey Photo* relied at least to some degree on evidence of consumer preference to find that the new camera-and-film combination was technically superior to preceding products. This logic holds true, however, only where consumer choice was unconstrained and at least somewhat informed. As noted *supra*, those conditions are rarely present in instances of software redesign. Instead of expressing that they “prefer” such redesigns, users generally “accept” them.

Consumer choice in this area is often constrained by software companies requiring users to accept and install software updates in order to continue using the program or all of its features. Witness, for example, Apple’s requirement that iTunes users download its allegedly exclusionary software updates in order to access the iTunes Music Store.⁷⁷² Unlike in *Berkey Photo*, the choice here was not between buying a competitor’s product and buying the dominant firm’s product. Rather, the choice that modern consumers must increasingly face is between being able to continue to use a familiar, already-owned product and either losing that ability or being forced to continue using a less-functional version of the same product. Given switching costs, particularly in closed network markets, consumer acceptance can hardly be said to be “unconstrained” in such scenarios.

Further, as noted above, the dominant trend toward automatic software updating means that consumers are not allowed to make a meaningful, informed choice as to whether to accept an update.⁷⁷³ And even before automatic software updating became the dominant method of code-based product redesign, little information was generally available to users. Since customer “choice” is neither unconstrained nor informed, antitrust courts must be extremely cautious in considering it as evidence of a technical improvement to a code-based product.

E. Shifting Burdens, Yet Avoiding Both “Balancing” and a Defendant-Friendly Default Rule

⁷⁷¹ See Aspen Skiing Co. v. Aspen Highlands Skiing Corp., 472 U.S. 585, 603 (1985) (“In [monopolization offenses] evidence of intent is merely relevant to the question whether the challenged conduct is fairly characterized as ‘exclusionary’ or ‘anticompetitive’ . . . .”).

⁷⁷³ See *supra* Part IV.B.2.b (discussing the trend toward automatic software updates and its implications for consumers).
A burden-shifting analysis offers a rational, useful, and efficient way for courts to approach claims of anticompetitive conduct, particularly design-related claims in the product markets under discussion here. As the party that bears the ultimate burden of proving its case, the plaintiff must first make a prima facie showing that the defendant has engaged in exclusionary conduct. The burden then shifts to the defendant to show a procompetitive justification for its actions. If the defendant fails to do so, the inquiry ends. And under the analyses employed in many product-design cases, if the defendant succeeds in doing so, the inquiry also ends. But as shown above, the rationale for such defendant-friendly analyses does not hold in code-based product markets (and especially markets characterized by positive network externalities). Thus, the burden should shift back to the plaintiff, allowing the opportunity to rebut that justification. If the plaintiff can do so, the conduct is rightly deemed unlawful.

But where the plaintiff fails to rebut the justification, courts would seem to be forced into an unpleasant choice between (1) attempting to “balance” the anticompetitive effects against the procompetitive justification, or (2) adopting a “tie-goes-to-the-runner” default rule favoring the defendant. The problems that inhere in a balancing test have been extensively documented and may even be exacerbated in the realm of product-design conduct, where such a test would require courts to “balance” anticompetitive effects against the benefits of innovation—a task that may well be workable in clearer cases but could be so fraught with uncertainty as to preclude any meaningful analysis of close cases. Yet a default rule favoring defendants is, as noted above, generally inappropriate in addressing code-based-product-redesign claims (particularly in network markets).

In the realm of code-based product redesign, however, this dilemma is largely illusory. Given (1) the unique separability of coded functions from a code file as a whole, and (2) the fact that code can be configured multiple ways to perform the same function, design-related conduct that truly causes both anticompetitive effects and constitutes procompetitive innovation will be at most extremely rare, and likely nonexistent. Thus, as in Microsoft III (and quite possibly In re Intel), many defendants that have engaged in anticompetitive conduct will likely not be able even to show a

275 AREEDA & HOVENKAMP, supra note __. At least in the realm of unilateral conduct, such a rule favoring plaintiffs has neither been adopted nor urged, given the difficulties that inhere in achieving and maintaining monopoly power.
276 See, e.g., Allied Orthopedic Appliances Inc. v. Tyco Health Care Group LP, 592 F.3d 991, 1000 (9th Cir. 2010) (“To weigh the benefits of an improved product design against the resulting injuries to competitors is not just unwise, it is unadministrable. There are no criteria that courts can use to calculate the ‘right’ amount of innovation, which would maximize social gains and minimize competitive injury. A seemingly minor technological improvement today can lead to much greater advances in the future.”).
277 One need not use a very precise scale to determine that an elephant weighs more than a chicken.
278 See supra notes __ and accompanying text.
plausible procompetitive justification. In the cases in which a plausible justification is shown, close examination at a low level of abstraction will generally reveal the effect of each coded function. Finally, antitrust courts should keep in mind the fact that code can be configured multiple ways to perform the same function, making truly ambiguous cases very rare. If a court finds itself seemingly unable to determine whether a defendant’s conduct was anticompetitive or innovative, it should go back and take a hard look at the alternative methods of designing the code that were, ex ante, available to the defendant. To the extent that intent can be ascertained, it could also be considered at this point. Thus, courts employing a burden-shifting analysis should be enabled to identify anticompetitive conduct with an acceptably low rate of false positives, all while avoiding both the uncertainty of balancing close cases and an inapposite default rule.

VI. CONCLUSION

The new economy has brought with it a host of innovations that have vastly benefited consumers and society. Yet it has also opened novel avenues for firms to engage in exclusionary conduct, creating the potential for untold harm to both consumer and total wealth. As shown above, the distinctive aspects of these markets and the products they comprise uniquely incentivize firms to engage in anticompetitive design-related behavior—here, perhaps more frequently than in any other markets, \( C_i > P_m - LR \). Fortunately, these aspects also render code-based product redesign uniquely susceptible to antitrust scrutiny. They also allow courts to apply a burden-shifting analysis that avoids balancing. Perhaps more importantly, they allow courts to properly avoid employing a defendant-friendly default rule that would reduce \( R \), further tipping the balance toward incentivizing harmful exclusionary conduct.

After decades of debate over the principles and ideology of antitrust law, some consensus has emerged regarding core antitrust values. The resulting “antitrust doctrine is supple enough, and its commitment to economic rationality strong enough, to take in stride the competitive issues presented by the new economy.” Despite this measure of doctrinal accord, however, some continue to criticize antitrust’s institutions as unwieldy or its rules as unfocused. This article seeks to allay those concerns. Given a proper understanding of code-based product markets and a structured, efficient, and rational method of analyzing design-related conduct in those markets, antitrust’s institutions will also be well-equipped to protect competition in such markets—and can do so without stifling true innovation.

279 This is particularly true of programs written in relatively higher-level programming languages. See supra notes ___ and accompanying text.
