Available at: https://works.bepress.com/jonathan_wickert/22/
An apparatus of reducing unwanted brake noise has a ring damper affixed around a periphery of brake drum in a drum brake system in a manner that permits relative motion and slippage between the ring damper and the brake drum when the brake drum vibrates during braking. In a preferred embodiment, the ring damper is an almost circular ring that is inserted in a groove formed in the periphery of the brake drum. The ring damper is held in place by the groove itself and by the interference pre-load or pre-tension between the ring damper and the brake drum.

1. DAMPER FOR BRAKE NOISE REDUCTION
(BRAKE DRUMS)

This application is a continuation-in-part application of U.S. Ser. No. 08/761,879 U.S. Pat. No. 5,855,257 for a damper for brake noise reduction filed Dec. 9, 1996, which is incorporated herein by reference.

This invention relates to brake noise reduction, and more specifically, to the use of dampers affixed to brake drums in drum brake systems to reduce brake noise during the braking process.

BACKGROUND

Drum brakes are commonly used in automobiles, trucks, buses, off-road and construction vehicles, and light rail vehicles. In a drum brake type of braking system, a drum that rotates with the vehicle’s wheel surrounds a stationary brake shoe arrangement. When the brakes are applied, the brake shoes are pressed against the inner surface of the brake drum by wheel cylinders under high hydraulic pressure. The frictional forces between the shoes and drum bring the vehicle to a stop.

A common problem associated with brake systems is that unwanted noise and vibration are often generated during the braking process. This unwanted noise is a frequently recurring problem that causes numerous customer complaints and significant warranty expenditures on the part of motor vehicle manufacturers.

It is an object of this invention to reduce brake noise.

It is a further object of this invention to reduce unwanted brake noise by the use of a simple damping arrangement that minimizes the amount of additional forming operations required in the manufacture of the brake system.

SUMMARY

An apparatus and method of reducing unwanted brake noise in accordance with this invention is a ring damper that is affixed to a brake drum in a manner that permits relative motion and slippage between the ring damper and the brake drum when the brake drum vibrates during braking. In one preferred embodiment, the ring damper is an almost circular ring that is inserted in a groove formed in the outer periphery of the brake drum. The ring damper can also be a set of rings; a multiple-wrap spiral shaped ring; or a wave shaped ring. The ring damper is held in place by the groove itself and by the interference pre-load or pre-tension between the ring damper and the brake drum.

In a preferred embodiment, the ring damper is pre-loaded against the brake drum both transversely and radially, preferably by means of elastic deformation of the ring damper. In the case where the ring damper comprises multiple damping elements, the damping elements are pre-loaded against each other and the brake drum by elastic deformation of a structural member which also forms one of the damping elements. This renders brake drum-to-damper pre-load insensitive to brake drum and/or damper dimensional variations that arise from thermal expansion and distortion, manufacturing tolerances, and brake drum vibration. In another preferred embodiment where the ring damper is a wave shaped ring, the pre-load is established by elastic deformation of the wave ring, which also provides damping.

BRIEF DESCRIPTION OF THE DRAWINGS

Additional features and advantages of the invention will become apparent to those skilled in the art upon consider-
following this relationship, one skilled in the art of brake drum design could heuristically determine the optimal value of the pre-load.

Referring to FIGS. 4A-4C, a ring damper 16 affixed to brake drum 10 according to this invention can include ring damper 16 received on the outer surface 20 of drum portion 14 and encircling, at least in part, the perimeter of drum portion 14 (FIG. 4A); ring damper 16 received in groove 18, as has been described (FIG. 4B); and a plurality of ring dampers 16 received in a plurality of grooves 18 (FIG. 4C).

Referring to FIGS. 5A-5D, the ring damper according to this invention and the outwardly opening groove formed in drum portion 14 can have different cross-sections, such as rectangular, ring 16 and groove 18 shown in FIG. 5A, circular, such as ring 22 and groove 24 shown in FIG. 5B or oval, such as ring 31 and groove 32 shown in FIG. 5E. The ring damper according to this invention can also comprise a single ring, such as rings 16, 22 and 31 shown in FIGS. 5A, 5B 5E, or multiple rings, such as rings 28 and 30 shown in FIGS. 5C and 5D.

Referring to FIGS. 6A-6C, the ring damper according to this invention can comprise a single wrap ring 34 (FIG. 6A), a multiple wrap ring 36 (FIG. 6B), or a wave shaped ring 38 (FIG. 6C). FIG. 7 shows wave shaped ring 38 in groove 18 in drum 10. FIG. 8 shows wave shaped ring 38 in groove 18 in drum 10 along with adjacent straight rings, such as ring 34.

With reference to multiple ring embodiments, such as shown in FIGS. 5C, 5E and 8, one of the multiple rings is preferably shaped so that when it is received in the groove 18, it elastically deforms to pre-load the multiple rings against each other and the drum.

The optimum number and location of ring dampers 16 used, the pre-loading of each, the shape of the cross-section of ring damper 16, the number of wraps around the drum for the multiple wrap embodiment (FIGS. 5C and 5D), the shape of groove 18, the surface treatment of ring damper 16 and groove 18 to establish functional characteristics, and the material used can be determined heuristically for each type of brake drum by one skilled in the art of brake design to optimize the damping of brake noise and vibration.

Although the invention has been described in detail with reference to certain preferred embodiments and specific examples, variations and modifications exist within the scope and spirit of the invention as defined in the following claims.

What is claimed is:

1. A brake drum having a ring damper around a periphery of the brake drum that is pre-loaded against the drum both transversely and radially and affixed such that said ring damper moves and slips between the ring damper and the brake drum when the brake drum vibrates during braking to damp brake noise.

2. The apparatus of claim 1 wherein the brake drum has a groove formed therein, the ring damper received in the groove and held therein by the groove and pre-loading between the ring damper and the brake drum.

3. The apparatus of claim 2 wherein the ring damper comprises a split ring.

4. The apparatus of claim 2 wherein the ring damper is formed in a wave pattern around the periphery of the brake drum.

5. The apparatus of claim 2 wherein the ring damper comprises multiple wraps of wire around the periphery of the brake drum.

6. The apparatus of claim 2 wherein the ring damper has a rectangular cross-section.

7. The apparatus of claim 2 wherein the ring damper has an oval cross-section.

8. The apparatus of claim 2 wherein the brake drum has the groove formed in its periphery.

9. The apparatus of claim 2 wherein the brake drum has the groove formed in its periphery.

10. The apparatus of claim 2 wherein the ring damper comprises first and second opposed straight rings and a wave-shaped ring sandwiched therebetween, the first and second opposed rings and wave-shaped ring pre-loaded against each other and transversely and radially against the drum by elastic deformation of the wave-shaped ring.

11. The apparatus of claim 2 wherein the ring damper comprises multiple rings, at least one of the multiple rings shaped so that when it is received in the groove with the other rings it elastically deforms to pre-load the multiple rings against each other and the drum.
