Definition of Health

Background
World Health Organization defines health as “a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity” (World Health Organization, 1948). This definition connects health with an individual’s entire life. On the other hand, the Public Health Agency of Canada defines health as “a capacity or resource rather than a state”, it “corresponds more to the notion of being able to pursue one’s goals, to acquire skills and education, and to grow” (Public Health Agency of Canada, 2012). Both definitions provide the context in which lifestyles, backgrounds, health services and social and economic conditions constitute the determinants of health, which impact and are impacted by, health. The definition of health provides guidance about how health outcomes should be measured and what factors should be included in health assessments. Hence, when assessing health or designing health interventions, a population’s definition of health is paramount.

Our Approach
In Phase I of the Black, African and Caribbean Canadian Health (BLACCH) Study, a purposive sample of 22 community members and 8 service providers aged 16 and older were interviewed. Community members were asked to define and rate their health, and service providers were asked to state their philosophy about health and characterize the health of local African, Caribbean and other Black (ACB) communities. In Phase II of the research project, 188 self-identified ACB people residing in London and area completed a paper-based survey. All survey participants were aged 18 and over. They were asked questions about their social condition and general health, among other things. Below, we present a summary of responses from Phases I and II that pertain to the definition of health.

Key Findings
Phase I: Community members said that health was a top priority for them, and they defined it holistically—it was physiological, emotional, spiritual and psychological. Health was not separated from quality of life.

I think health to me is a perfect wellbeing, both physical, mental, and spiritual and…it means everything because it’s being able to have a good life – being able to live well. (Black American Female)

Community members generally thought they were in good health until they had fallen ill. When asked about how migration impacted their health, they either said that their health remained the same or deteriorated after migrating.

So I think the only difference was I had to be, to make more of a conscious effort to be healthier in Canada as opposed to [MY HOME COUNTRY]. (African Female)

Like community members, social service providers viewed health holistically, and they saw disease prevention as an important aspect of health. On the other hand, health service providers talked about the importance of individuals taking charge of their own health and being able to access health care. Overall, health service providers said that ACB people needed to take their health more seriously.

When it comes to health, the most important thing about any diagnosis is learning about it, getting adequate information, and then making sure that you are doing what is required to be healthy. (ACB Female)

Lots of times you hear them say that, oh, my cholesterol is high, my blood pressure is high, but they actually just say it without realizing that it is serious. So I find that the people that I know, they know that they have issues but they don’t see it as a problem. (ACB Female)
Phase II: Most participants (91%) said their health had either stayed the same or diminished over the past year (Table 1), but the majority of participants rated their general (69%) and mental (73%) health as “very good” or “excellent” (Figure 1). Furthermore, only 77% of participants had seen a health care provider in the past year (Table 2).

Table 1: Comparing Current Health to Last Year’s Health

<table>
<thead>
<tr>
<th>Comparison</th>
<th>Num.</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Much worse now than 1 year ago</td>
<td>41</td>
<td>22</td>
</tr>
<tr>
<td>Somewhat worse now than 1 year ago</td>
<td>19</td>
<td>10</td>
</tr>
<tr>
<td>About the same as 1 year ago</td>
<td>110</td>
<td>59</td>
</tr>
<tr>
<td>Somewhat better now than 1 year ago</td>
<td>16</td>
<td>9</td>
</tr>
<tr>
<td>Much better than 1 year ago</td>
<td>1</td>
<td>0.5</td>
</tr>
<tr>
<td>Missing</td>
<td>1</td>
<td>0.5</td>
</tr>
<tr>
<td>Total</td>
<td>188</td>
<td>100</td>
</tr>
</tbody>
</table>

Although the majority of participants (54%) said they were satisfied with their lives (Table 3), most (63%) said their lives were at least a bit stressful and 36% said their daily lives had little or no stress (Table 4).

Impact on Policy and Practice

These results show that ACB communities and social service providers define health similarly to the World Health Organization and the Public Health Agency of Canada. Hence, a strictly physiological definition of health is inappropriate for these communities and the people providing services to them. Furthermore, an individual’s social condition impacts his/her quality of life and through that, his/her health. To more fully address health in ACB communities, it is important that health interventions consider social factors that impact these communities and are sources of stress, dissatisfaction, lack of empowerment and reduced health care access. Also, community members should be involved in the development of these interventions to ensure that their outcomes are consistent with these communities’ definition of health.
